CARRIER SQUELCH/PL SOFTWARE DESCRIPTION

STORNOPHONE 5500

The CQM5500 radio is offered in several tiers with differing capabilities regarding Private-Line (PL) and Select 5. This document describes the operation of the Carrier Squelch (CS)/PL radio.

Many features of the CS/PL radio were implemented to meet various customer requirements. Some of these features offer more flexibility and user friendliness than previous radios. A good example of this is the one-hand operation which allows the operator to receive in the coded squelch mode even when the microphone is not on hook.

DEFINITIONS

Channel

Transmit and receive frequencies plus data that:

1. Points to one radio mode.
2. Selects one of two synthesizer reference frequencies.
3. Selects high or low transmit power.

Trakmode

When the radio is programmed with more than one mode and each channel has one of these modes associated with it. Each mode may be used with more than one channel.

Mode

A radio operation state programmed in EEPROM consisting of:

1. A PL decode frequency.
2. A PL encode frequency.
3. A "receive enable" bit.
4. A "monitor enable" bit.
5. A "PL decode enable" bit.
6. A "PL encode enable" bit.
7. A "transmit enable" bit.
8. A "disable transmit channel when channel is busy" bit.

NOTE

The PL frequencies are actually pointers into a frequency look-up table.

Monitor mode

The radio is in the "monitor" mode if carrier (noise squelch) is selected or if the radio is unsquelched.

Coded squelch

When the radio unmutes as a result of decoding PL.

STORNOPHONE 5500 CARRIER SQUELCH/PL SOFTWARE DESCRIPTION

AUDIO CONTROL/ONE-HAND OPERATION

Many radio operators do not replace the microphone in the hang-up box (HUB) when they are done with a conversation. Most radios will stay in the carrier squelch mode (which can annoy the operator since he will hear all channel traffic) until the microphone is placed in the hang-up box. The CQM5500 radio handles this in a different manner.

One-hand operation automatically places the radio in the coded squelch mode 7 seconds after PL was last decoded, regardless of the HUB state. If the operator does not want to wait the full 7 seconds he may press the reset button (which is shared with the monitor button) or place the microphone on-hook. Also, changing channels will reset the timer.

Once the radio is in the coded squelch mode, the carrier squelch mode is entered (and the 7 second timer begins) when the operator goes off-hook or presses and releases the PTT button. While in the carrier squelch mode, any time the operator de-keys, or any time PL is decoded, the timer will reset to 7 seconds.

The term "one-hand operation" was chosen because the operator can enter the carrier squelch mode and then transmit without ever having to remove his hand from the microphone. Radio operation described above (the 7 second timer, etc.) is called part of the one-hand operation although it is automatic. It is patterned after the Select 5 auto reset operation.

The EEPROM may be programmed to prevent a PL decode from overriding the 7 second timer. Also, the selection of the carrier squelch by pressing PTT may be disabled. Should the one-hand operation need to be totally eliminated, that may also be done by programming the EEPROM. Modifying any of these EEPROM bits would have to be done on an SP basis.

If one-hand operation is disabled, the radio will remain in the carrier squelch mode as long as the microphone is off hook. The coded squelch mode will only be enabled when the microphone is on-hook and the monitor switch is in the coded "position".

The muting of the radio is determined by several factors. These are:

- Monitor switch selection
- The radio mode data
- The one-hand operation timer.

Assuming that the one-hand timer is not active (it has timed out), the radio will be in the coded squelch mode (PL) if the monitor switch is in the coded "position" and the radio mode has "PL decode" enabled. If not, the radio will be in the carrier squelch mode.

There is one exception to the above discussion. When the monitor switch is in the "unsquelch" position, the radio will unmute and remain unmuted until the monitor switch is changed. The only thing preventing the radio from unmuting is if the radio mode does not allow monitoring or reception on the channel.

The monitor switch is a momentary switch which the command board processor reads. It is used to select three "positions" which are used to determine the proper muting mode. The term "position" is used because the switch is functionally treated as a latching mechanical switch. An annunciator above the switch (high-tier control head only) indicates the "position" of the switch. One "position" selects the carrier squelch mode and the annunciator is turned on. Another "position" selects the unsquelch mode and the annunciator is flashing even when the switch is pressed for at least 500 milliseconds. One other function of this switch is to reset the one-hand operation 7 second timer when it is active. When this occurs, there is no change to the "position" of the switch.

A yellow LED indicates the radio muting mode. If the LED is on, it means that the radio is in the monitor mode (carrier squelch or unsquelch). If the LED is off, it means that the radio is in the coded squelch mode.

STORNOPHONE 5500 CARRIER SQUELCH/PL SOFTWARE DESCRIPTION

Usually the annunciator above the monitor switch and the LED will agree. However, it is possible for the annunciator to indicate that the switch is in the coded squelch "position" but the LED is on because the radio is in the monitor mode. One instance is when a channel is selected that does not have PL decode enabled.

Operation using a low-tier control head is identical except there is no LCD so the annunciator is not used. AND squelch is available as an SP. This simply requires that, when in the coded squelch mode, both a "PL decode" and a "carrier detect" must be present before the radio will unmute.

CARRIER SQUELCH ONLY

The "carrier squelch only" radio has a few differences in operation compared to the PL radio. The first is that the yellow LED is never on since it is not needed. If it was used to indicate the monitor mode (as in the PL radio) it would always be on. The second is the operation of the monitor switch. Since there is no coded squelch position now, there are only two "positions" allowed and these are carrier squelch and unsquelch. The monitor switch must still be depressed at least 500 milliseconds to enter the unsquelch mode. Since the coded squelch "position" is not allowed, the annunciator will always be either solid (carrier squelch mode) or flashing (unsquelch mode) when a high-tier control head is used.

CHANNEL CHANGE DISPLAY AND WRAPAROUND

The low-tier control head uses two LED's for the two-channel radio to indicate the current channel. One-channel radios have no channel indicator LED's.

When a high-tier control head is used, the situation is much more complex. One or two digits in the display are used to indicate the selected channel. The operation differs depending on the maximum number of channels programmed for the radio.

If the radio is programmed for a maximum number of channels less than ten, then the operator has one button to press in order to change channels. The displayed channel number will increment once per button pressed until the highest numbered channel is reached. Pressing the button once will wrap around to channel 1.

If the radio has two or more channels, then two buttons are used to select the desired frequency. The "units" button affects only the units of the channel number and will increment from 0 to 9 and then wrap around. The "tens" button will increment from 0 (which is displayed as a blank) to the number of tens in the largest channel number. If the radio is programmed for 32 channels, the "tens" digit will increment from 0 to 3 and then wrap around. Sometimes an invalid channel might be selected.

Consider the following example:

Assume that the radio has a maximum of 32 channels and that channel 25 is currently selected. If the operator wants to go to channel 8 he may choose to update his units first. He now has selected channel 28. Now it is time to update the "tens" digit. Pressing the "tens" button once displays channel 38 which is not a valid channel number. The number 38 will now be flashing to indicate it is invalid. The operator has 10 seconds to correct the channel number before it will automatically return to last valid channel (channel 28). By pressing the units button once more (before the 10-second time-out) channel 8 will be selected.

CONTINUOUS MEMORY

When the radio is properly installed, voltage will always be present at the power connector. When the operator turns the radio off using the switch on the control head, the microprocessor will turn off power to most of the radio's circuitry and place itself in a standby mode. Current drain during the standby mode is very small because the microprocessor is CMOS. The current state of the radio is preserved in the microprocessor memory (RAM) so that, when the radio is turned on again, the operator does not have to re-enter the channel number, etc.

STORNOPHONE 5500 CARRIER SQUELCH/PL SOFTWARE DESCRIPTION

For the high-tier control head, there are two exceptions. The first is that the state of the external PA (if this option is present) will always power on in the disabled state. The second is that the speaker override will not be active when a handset is used.

When a low-tier control head is being used, all information is preserved. One interesting point is to note that, since the channel select buttons control a latch that has power applied during standby, the channel selection can be changed even while the radio is in the standby mode. There is no indication of the change until the radio is turned on when power is applied to the LED's.

CONTROL HEAD

When a low-tier control head is used, the command board will directly poll the switches and control the LED's with a parallel interface. This is because the control head has no smarts. When the radio is placed in the programming mode, serial data is transferred between the command board and the computer on the microphone audio line and the PTT line.

When a high-tier control head is used, the command board will communicate serially with the control head microprocessor when a button is pressed or the display needs to be updated. The programming mode is similar to the low-tier control head situation except that the control head microprocessor will act like a pair of wires that connect the microphone and the PTT lines to the serial bus lines that are used during normal radio operation. This is necessary because, if microphone and PTT lines were hard-wired to the serial bus, this would interfere with normal radio operation serial bus activity.

EEPROM LIMITATIONS/MAXIMUM NUMBER OF CHANNELS AND MODELS

The command board software will support various configurations of EEPROM. These are:

1 - 128 x 8	(128 bytes)
2 - 128 x 8	(256 bytes)
1 - 256 x 8	(256 bytes)
2 - 256 x 8	(512 bytes)
1 - 512 x 8	(512 bytes)
2 - 512 x 8	(1024 bytes) MAB909

All radios require 56 bytes for system information and PL encode and decode look-up tables. The remainder of the EEPROM may be used for a combination of radio modes and channels. A maximum of 32 modes may be used since 5 bits of each channel are used to select a mode. All radios must have at least one mode. When more than one mode programmed, they are called Trakmodes because the mode will track the channel.

The following table shows some possible combinations of the maximum number of modes and channels as a function of the EEPROM size. These examples may not necessarily correspond to what is being sold as a standard offering. Six bytes of EEPROM are required for each channel and three bytes for each mode.

STORNOPHONE 5500 CARRIER SQUELCH/PL SOFTWARE DESCRIPTION

EEPROM Size	Number of channels	Number of trakmodes
1-128 x 8	8 11	8 1
1-256 x 8 or 2-128 x 8	22 32	22 2
1-512 x 8 or 2-256 x 8	60 75	32 2
2-512 x 8	99	32

ERROR TONES

There are certain circumstances that are prohibited and other conditions which are undesired that may occur during operation of the radio. Tones are generated during these situations to alert the operator.

The majority of error conditions occur when the operator presses PTT when transmission is not allowed. These situations prevail when:

- The radio is not in the monitor mode.
- The transmit time-out timer (TOT) has expired.
- The post-TOT PTT inhibit timer is active.
- The current channel does not allow transmission.

The generated tone has a frequency of 819 Hz and is continuous. The tone will stop only when the operator releases the PTT button. The frequency of 819 Hz was chosen because it is a multiple of the transmit interrupt rate.

A short (100 milliseconds) tone at 819 Hz is generated when the transmit time-out timer has 4 seconds remaining before the transmitter will be shut down.

If the synthesizer does not lock, an 819 Hz tone will be generated for 250 ms and 250 milliseconds off until lock is achieved. The synthesizer divider is re-loaded during the no-tone period in case the no-lock condition occurred as a result of noise on the data, sent to the divider.

If a button is pressed on a high-tier control head while transmitting, a short tone will be generated and the keypress will be ignored. If a button is pressed on the low-tier control head while transmitting, the transmitter is dekeyed, an error tone is generated and the radio changes the channel. However, the channel LED's are controlled by the channels buttons independently of the microprocessor.

If a hardware failure causes PTT to appear active constantly then an error tone will be generated when the radio is turned on until the problem is corrected or the radio is turned off.

HANDSET OPERATION

The handset essentially functions as a control head. The major differences are that the speaker and microphone are now in the same housing and the regular radio speaker may be disabled or enabled by pressing a button. This allows the operator to prevent other persons in the vehicle from hearing the receive audio.

STORNOPHONE 5500 CARRIER SQUELCH/PL SOFTWARE DESCRIPTION

KEY/DE-KEY TIMING

The order of events for keying the transmitter are listed below. First, the red LED is turned on. This will take about 20 milliseconds if the high-tier control head is used (if there is an error on the serial bus then this time will increase). The audio is then muted. About one millisecond is required to write to the latch to do this. Next, the transmit frequency is read from the EEPROM which takes about 6 milliseconds. The latch is updated to select either high or low power for the RF PA. This takes about one millisecond.

The synthesizer reference and frequency data is then written to the divider which takes about 5 milliseconds. Now, the processor waits for the synthesizer to lock. The delay is EEPROM-programmable and will be about 50 to 80 milliseconds, depending on which band is used. If the synthesizer is not locked when the delay time elapses, a short error tone will be generated and the synthesizer data will be re-written to it. This sequence repeats until the synthesizer locks. The delay time for the synthesizer to lock is also used to debounce the PTT switch. If PTT is no longer pressed after lock is achieved, then the synthesizer will be restored to the receive frequency, otherwise DPTT is turned on in order to enable power to the exciter. The approximate time, required from pressing PTT to enabling the transmitter, is 64 milliseconds when the low-tier control head is used and the synthesizer lock delay is 50 milliseconds.

If a high-tier control head is used with a radio that needs 80 milliseconds for the synthesizer to lock, then the time will be about 114 ms.

The order of events for de-keying the transmitter will now be described. When PTT is released, reverse burst will be generated for 180 milliseconds if PL is enabled. DPTT is then disabled and power is removed from the exciter. The red LED is turned off (timing is the same as the turn-on time mentioned earlier). The receiver VFO is selected by updating the latch. The receive frequency information is read from the EEPROM, the synthesizer is updated and a delay occurs before checking for lock (in a manner similar to the transmit sequence). The approximate times from PTT release to entering the receive mode are from 62 milliseconds to 272 milliseconds, depending on whether PL is enabled and which control head is used.

MULTI-PL DISPLAY AND OPERATION

Some radio operators need to use more than one PL code per channel. An example of this is when he has access to more than one repeater, each having different PL tones. The CQM5500 radio allows the operator to select up to 10 different PL codes by pressing a button on the high-tier control head. With this option, the display indicates the PL number (1-9 or 0) that is currently in use. Pressing the button will increment the display and the display sequence will be:

... 7890123456789012 ...

If less than 10 PL codes are desired, the EEPROM may be programmed accordingly. For example, assume that 5 is the maximum number of Multi-PL codes. The sequence will then be:

... 23451234512 ...

Note that, regardless of the maximum number of Multi-PL codes, there will always be room reserved in the EEPROM for 10 PL codes. In this discussion, PL code refers to the pair of encode and decode frequencies. The radio can be programmed to change only the encode frequency, only the decode frequency, or both frequencies when a new Multi-PL selection is made. When the channel is changed, the last selected PL will remain in effect for the new channel.

The radio may be SPed to allow use of Multi-PL and Trakmode together. This allows the operator to not only have the normal Trakmode features, but when the channel is changed, the PL selection programmed in the Trakmode may be used (this revert to mode PL is EEPROM selectable). When both of these options are selected, a (*) is displayed when the Trakmode-PL is selected. The display sequence will be:

... 890*1234567890*123 ...

STORNOPHONE 5500 CARRIER SQUELCH/PL SOFTWARE DESCRIPTION

OPTIONS/SP's/NON-STANDARD OPERATION

OPTIONS

Several options may be enabled by programming the EEPROM, adding the necessary hardware, or a combination of both. The CQM5500 USER GUIDE PROGRAMMER HANDBOOK describes how the EEPROM should be programmed to select certain options. The following are options offered for sale.

Options requiring only an EEPROM change

- Delete Time-Out Timer
- Non-Standard Time-Out Timer
- PL Decode only
- PL Encode only
- Delete Busy Light
- Multiple PL Encode (High-Tier Control Head)
- Multiple PL Encode/Decode (High-Tier Control Head)
- TX Inhibit on Busy Channel
- Trakmode
- 32 Channels (High-Tier Control Head)
- 20 Channels (High-Tier Control Head)
- 2 Channels (Low-Tier Control Head)
- RF Power Slaved to Channel

Options requiring only hardware changes

- Manual Public Address
- Handset

Options requiring EEPROM and hardware changes

- Low Tier Control Head

Special product features

There is flexibility in the radio for more options than will be offered for sale; these features must be enabled on an SP basis.

- Multiple PL Decode
- Up to 75 Channels
- Disable One-Hand Operation entirely
- Disable PTT Press to Enter Carrier Squelch Part of One-Hand Operation
- Disable PL Override of One-Hand Operation Timer
- Trakmode + Multi-PL
- No Revert to Mode PL at Channel Change when Trakmode + Multi-PL is selected.
- PL "AND" Squelch
- Allow TX without Monitoring (if legal)

Non-standard operation

Several modes of operation are EEPROM selectable in order to allow the CQM5500 to be used as a base station. These operations should never be enabled when the radio is used as a mobile. The following is a list of the non-standard operations:

Delete All Serial Data coming from the Radio Command Board (including echoes of data sent to it)

STORNOPHONE 5500 CARRIER SQUELCH/PL SOFTWARE DESCRIPTION

- Delete Only Command Board Originated Serial Data
- Allow PTT to Abort the Synthesizer Lock Delay of a receive frequency.

PL OPERATION

The PL encoder is a phase accumulator algorithm running at an interrupt rate of 122 microseconds. A 3-bit D/A is used to generate the sine-wave approximation. A 3-pole low-pass filter attenuates out-of-band distortion products. Distortion measured at the splatter filter output is less than 3% across the 67-250.3 Hz range of PL tones. Reverse burst is generated by advancing the phase 240 degrees and delaying 180 milliseconds before de-keying the transmitter.

The PL decoder is a correlation decoder running at an interrupt rate of 934 ms. It is basically a translation of the Syntor X PL decoder, except that the threshold is increased for PL tones less than 72 Hz to reduce the bandwidth in order to meet the RS220A specification which states that the tone must not be decoded if the frequency error is 3% or greater.

PROGRAMMING MODE

In order to program the radio EEPROM an external computer is connected to the radio. When connected, an NMI is generated. The processor will initialize all ports and the latch outputs to an idle state. Since the EEPROM contents may not be valid, the processor has no way of being sure of which type of control head is connected. In order to guarantee proper operation, the processor assumes a high-tier control head is connected and releases the control head reset line. A result of this is that, if a low-tier control head is used, the red LED will come on. The NMI line is poled via a resistor on a port so the processor will know when the computer has been disconnected. The normal radio mode of operation will commence when this occurs.

While in the programming mode, the processor will wait for a command to be sent from the computer. Any characters received that are not the beginning of a command sequence will be ignored unless they have incorrect parity, in which case a NAK will be sent to the computer.

Once the command board byte is received, the byte count and address are expected to come next. While waiting for these modified ASCII-hex characters to come, a NAK will be sent to the computer if ANY non-data character is received or if the parity is incorrect (this includes command bytes or NAK's from the computer). The processor has no time-outs while waiting for information from the computer. The computer is considered the master and performs time-out and memory verify operations. The main reason for this is to reduce the ROM burden of the radio processor. For a complete description of the modified ASCII-hex format, refer to the "CQM5500 User Guide Programmer Handbook".

NOTE

If the programmer board has a failure in the circuitry that generates the NMI, it is possible for the radio to transmit when the external computer is connected. The reason is that the PTT line becomes a data line from the computer when the programming mode is entered. If the processor does not know if the programming mode is true, then it will enable the transmitter while the computer controls the PTT line.

TEST MODE

The radio's only test is when the microprocessor is placed in reset so the circuitry it controls may be driven by an external source.

STORNOPHONE 5500 CARRIER SQUELCH/PL SOFTWARE DESCRIPTION

TIME-OUT TIMER

The time-out timer prevents the radio from continuously transmitting as a result of hardware failure in the PTT circuits or an operator who has transmitted for a lengthy amount of time. The time-out is EEPROM programmable in 5-seconds steps from 5 to 1275 seconds. The time-out can be disabled by programming the value to zero seconds. Four seconds before this time-out occurs, a short warning tone is generated to alert the operator that the time-out is near. When the time-out occurs, a continuous 819 Hz tone is generated until PTT is released. Before the transmitter is de-keyed, reverse burst is generated if PL encode is enabled.

In addition to the somewhat standard TOT there is another timer which prohibits transmission after the TOT occurred (or after the warning tone sounds). This forces the operator to wait an amount of time before he may transmit again and helps reduce abuse of the channel. This inhibit time is also EEPROM-programmable in one-second increments from zero to 255 seconds.

TX POWER SELECT

The RF power output can be selected to the channel-dependent. There are two levels (high and low) which are set to the desired power by adjusting potentiometers inside the radio.

3

THEORY OF OPERATION

STORNOPHONE 5500

RECEIVER

FRONT END (Reference Designators)

The received signal applied to the radio's antenna input is routed through the harmonic filter/antenna switch, located in the RF power amplifier compartment. The attenuation due to this path is 0.8 dB maximum. The output is applied, via a coaxial cable, to J1 on the RF board. L8 and C17 form a high-pass filter which provides additional attenuation to signals below 66 MHz, particularly the 21.4 MHz IF frequency. L1 through L4 and associated components form a shunt-coupled bandpass filter having a 3 dB bandwidth of 8 MHz and a 1 dB bandwidth of 4.5 MHz. The center frequency of this filter may be tuned anywhere from 66 to 88 MHz and allows receiving signals within 2 MHz either side of the center. This filter configuration provides more rapid attenuation above the passband than below. Since high-side first injection is used, this response is desirable as it provides greater attenuation of receiver spurs such as the "half IF" and image. The output of this filter is routed to the gate of the first mixer Q1 and presents a source impedance of approximately 800 Ohm. Resistor R3 provides a DC return for the gate.

The synthesizer provides a receiver injection signal at a frequency 21.4 MHz above the desired receive frequency and at a nominal level of +13 dBm. This signal is filtered by the injection filter, L5 through L7 and associated components. This filter has a 3 dB bandwidth of 7.5 MHz and a 1 dB bandwidth of 4 MHz; it is tuneable between 87.4 MHz and 109.4 MHz. It provides attenuation of injection noise at the receive frequency (21.4 MHz below the injection signal) and for this reason, it has a more rapid attenuation below its passband than above. The filtered injection signal is applied to the source of first mixer Q1.

Q1 has a conversion gain of 9 dB. The IF signal appears across L51, which resonates with C18, C52 and C53 at 21.4 MHz. C18 provides bypassing of very high frequency stray inductances which may lead to instability of Q1.

Q1 is biased by R2 at 5 mA with no injection signal. This current increases with injection and for this reason, the DC source voltage may be used as a means of tuning the injection filter for minimum insertion loss. This tuning is normally done at or near the center of the desired receive passband. R1 isolates the detuning effects of the voltmeter probe.

RECEIVER IF, DETECTOR AND SQUELCH STAGES

The output of the first mixer is filtered by a 4-pole, 21.4 MHz monolithic crystal filter (Y51) consisting of two 2-pole filters Y51A and Y51B. Capacitors C52 and C56 provide the correct matching and coupling impedance required by these filters. The impedance and, therefore, the component values are different, depending on whether 20/25 kHz or 12.5 kHz channel spacing is used. The 3 dB bandwidth of Y51 is 15 kHz minimum for 20/25 kHz applications and 7.5 kHz minimum for 12.5 kHz channel spacing applications.

The output of Y51 is applied to a two-stage buffer, Q51 and Q52. Q51 is a common-source voltage amplifier which is direct-coupled to Q52; it operates as a current source having very high output impedance. The output voltage, developed across the resonant network L53 and C54, C64 fUm, is applied (via C69), C65 fUm, to the input of the second mixer, U51 pin 19.

Diodes CR51 and CR52 prevent overload by very strong signals (greater than 100 mV) at the antenna input. CR51 prevents overloading of buffer stages Q51 and Q52. CR52 prevents the amplified output of the buffer from overloading the second mixer in U51.

STORNOPHONE 5500 THEORY OF OPERATION

Injection for the second mixer is obtained from an oscillator transistor whose base is U51-15 and whose emitter is U51-16. The frequency is determined by crystal Y52; it is normally 20.945 MHz but may be changed to 21.855 MHz if its harmonics interfere with a desired receive signal. In either case, the resulting second IF frequency is 455 MHz.

The second oscillator level is adjusted by divider C62 and C63. The oscillator signal, present at the top of C63, is coupled to the input of the second mixer in U51 by C64 which forms part of the output resonant circuit of the buffer.

Resistor R56 increases the bias current of the second mixer for more consistent performance over a wide temperature range.

The output of the second mixer U51-20 is applied to ceramic filter FL51. The output of this filter is fed into U51-21 where it is amplified approximately 30 dB and applied via U51-23 to the second ceramic filter FL52. Each of these ceramic filters has an insertion loss of approximately 3 dB and a bandwidth which is at least one and a half times wider than the corresponding crystal filter used in the high IF. This ensures that temperature drift in the ceramic filter elements will not degrade the receiver's passband response, while still obtaining significant attenuation of adjacent channel signals. Like the crystal filters, different ceramic filters are used for 20/25 kHz vs. 12.5 kHz channel spacing models.

The output of the last ceramic filter is applied to U51-24 where it is applied to a series of high-gain limiter/amplifier stages having an overall gain of at least 70 dB. U51-24 is also used as a convenient IF gain measurement test point, since it is behind all selectivity elements but before any non-linear (limiting) gain stages. A high impedance voltmeter, capable of reading 455 kHz signals, should indicate approximately 30 mV at this point when -85 to -95 dBm is applied to the receiver's input. The level at this pin will saturate out at approximately 150 mV RMS, and no further increase in level above this value will be seen as the receiver input level is raised.

The high-gain limiter stages are followed by a quadrature detector which uses L54 as a phase-shift element. L54 produces a varying phase vs. frequency response, and is tuned for 90° phase shift at 455 kHz. A multiplier compares the direct and phase-shifted IF signal and produces either no output when the two signals are in quadrature (90° phase difference), or a varying amount of DC offset voltage as the two phases differ. Thus, an AC signal is produced which is proportional to the FM modulation of the IF signal. Unlike a discriminator, there is a DC offset (typically 2.3 V) for an unmodulated, on-channel carrier. The variations, produced when modulation is applied, amount to typically 15 mV RMS per kHz of deviation, measured at U51-5. An active 3 pole low-passfilter reduced outband noise above 3 kHz. This audio is applied via R62 to J3 pin 10, where it goes to the receiver low-level audio stages on the command board. The value of R62 changes for 12.5 and 20/25 kHz channel spacing models, providing a consistent audio level for 60% of full system deviation. This keeps the audio reserve gain, signalling detector audio levels, etc. constant for different channel spacings without the need to change values on the control board.

A part of the audio signal at U51-5 is also applied (via R60 and C76) to U51-7, the input of the carrier squelch circuit. This signal is amplified and appears at U51-6, is adjusted by the SQUELCH control R59, and fed back to U51 (pin 8). C75 and C78 help shape the lower and upper frequency band limits. The presence or absence of noise is measured by a detector whose output is U51-11. This pin is high (4.6 V DC typical) with no on-channel signal, and goes low when a signal of sufficient quieting is received. A two-time constant circuitry provides RF-level dependent attack- and delaytimes. This output is buffered by Q53 and routed to the control board microprocessor circuits via J3 pin 9. The squelch setting is nominally 9 to 11 dB SINAD CCITT weighted.

STORNOPHONE 5500 THEORY OF OPERATION

HIGH-TIER CONTROL BOARD

DC DISTRIBUTION

The CQM5500 control board has two regulated voltage sources that provide 5.0 and 9.6 V. The 5 V source supplies power primarily to the microprocessor, the serial latch (U705) and the memory device U702. The 5 V supply is always on, even when the radio is turned off, provided that the radio is properly installed (battery voltage is always present on B +).

Since CMOS devices are used, the current drain from the 5 V source is negligible when the radio is turned off. The memory chip is also CMOS but power is completely turned off to it via Q702 except when it is being accessed during normal radio operation. The 5 V source is also used to power various transistors used for interfacing and buffering purposes.

The 9.6 V source is turned on and off by the microprocessor. It primarily supplies power to the filters, limiters, amplifiers, and RF board via P3-7. The microprocessor turns off the audio by causing U705-5 (the latch) to go low. This removes power from U401 which disables the 9.6 V regulator circuit and transmit power control circuitry.

A 4.8 V source is derived from the 9.6 V source using a resistive divider (R408 and R409) and filter capacitor (C405). This is used to bias various operational amplifiers.

The audio PA output stage is powered by B +. The microprocessor turns off the audio by causing U705-4 to go low which turns off U704F (transistor) and Q508. The biasing of the output transistors is removed and no current is drawn by them.

NOTE

The battery should always be connected to the radio, no matter whether the radio is turned on or off. This allows the continuous memory function of the radio to operate.

POWER UP (Initial battery connection)

When the battery is initially connected to the radio, C707 begins charging. While it is charging, the outputs of the serial latch (U705) are tri-state. This guarantees that U705-5 will be pulled high by R762 to allow the microprocessor to come out of reset (U701-6, 7 will go high). The watchdog timer's output Q902 is also off during this time in order to allow U701-6, 7 to go high. C902 in the watchdog circuit is discharged (0 volts across it) which places 9.6 V on U601-14. Since U601-13 is about 2.5 V, U601-12 will go low (1.4 V). The divider, formed by R904 and R908, is such that the transistor will be tuned off.

U701-7 immediately goes high and the microprocessor comes out of standby. CR703 forces U701-6 (reset) to rise slowly as C705 begins to charge and the oscillator Y701 begins operation. While the voltage at C701-6 is less than about 4 V, all I/O lines of the microprocessor are high impedance. The microprocessor's mode of operation is selected by JU706 and JU707 (see jumper table below).

Once C705 has charged, the microprocessor comes out of reset and begins executing its operating program. The microprocessor will toggle the clock and data lines via U701-11 and U701-10 respectively. The serial data activity will tickle the watchdog timer in order to prevent it from resetting the micro-processor. The clock and data lines are used to write data to the latch (U703) and the synthesizer via P3-4 and P3-3.

After data is written to the latch, a positive-going pulse is generated on U701-16 to enable new data to be written to the latch output. U703-5 will be high in order to enable the 9.6 V supply.

STORNOPHONE 5500 THEORY OF OPERATION

The control head LED's and LCD display will be initialized by the processor. The synthesizer will be initialized to the proper channel by sending information on the clock and data lines. Once the data is sent, U701-32 will generate a pulse in order to latch the data.

Jumper Table

POWER DOWN

The radio will operate as long as the switch on the control head is on. When it is turned off, Q705 will turn off, U701-24 will go high and the microprocessor will cause the latch (U703-5) to go low, which turns off the 9.6 V supply and allows standby/reset to occur (U701-7, 6 are low).

Q704 will be off when the emergency switch is not pressed (emergency option) or when JU710 is installed. Q705 will be off when the microprocessor turns off the 9.6 V supply. When all three of these transistors (Q704, Q705, and Q706) are off then Q707 will turn on and put the microprocessor into standby/reset. If any one of Q704, Q705, or Q706 is on, the microprocessor will not be in standby/reset.

The microprocessor still has power applied to it and it maintains the current status of the radio (channel number, muting mode selected and other operator-selected information). When the radio is turned on by the control head switch then the radio status is restored to what it was before the switch was turned off.

CONTROL HEAD INTERFACE

The high-tier control head uses an LCD and LED's to indicate the current radio status. Momentary switches are used for changing the channel and other functions. The low-tier control head is not compatible with the high-tier control head board.

The microphone PTT switch controls Q712 via J4-2 and is read at Q701-18. The Hang-Up Box (HUB) switch controls Q710 via J4-7 and is read at U701-21. Receive audio is routed to the control head volume control at J4-3. The volume-dependent audio is returned to the command board at J4-11 and sent to the audio PA. The speaker connections at J4-5 and J4-12 serve the purpose of connecting a speaker to the control head when a remote-mount radio installation is used.

The control board communicates to the high-tier control head (serial control board) over a 2-wire asynchronous data link (Q708, J4-8 and Q709, J4-15). Please note that this serial link is different than the synchronous serial bus, used to control the serial latch and synthesizer. The control head has a microprocessor in it that processes button presses, LED display, and LCD display. Using a serial data protocol, information is exchanged between the processors to update the display or change the current status of the radio. Asynchronous 7-bit data with odd parity is sent at 1200 baud in a half-duplex manner (the control head processor is duplex). J4-1 and J4-9 are spare lines and are not used.

STORNOPHONE 5500 THEORY OF OPERATION

PROGRAMMING MODE

When the radio needs to be customized for a particular customer's channel and other radio information, a computer is connected to the radio and the data is programmed into the EEPROM. The computer may be interfaced directly to J4, or it may be connected to the radio through the microphone connector. In either case, the special programming mode is entered by raising the voltage on the HUB line (J4-7) to at least 5 V. This will cause Q714 to turn off and generate a non-maskable interrupt to the microprocessor. The microprocessor will stay in the programming mode as long as U701-8 (NMI) is low. Since the microprocessor cannot read the state of U701-8 directly, it reads it at U701-15 via R766.

When the processor sees a high at U701-15 it will exit the programming mode and begin normal operation. This allows recovery in case noise caused the programming mode to appear active momentarily.

If a high-tier control head is connected during the programming mode then the control head processor will rapidly read the PTT line and echo the information to J4-8 to get the data from the computer to the control board. Likewise, data from the control board at J4-15 will be rapidly read and echoed to the microphone audio pin of the microphone connector. Note that this control head operation is true only when it senses that the programming mode is active.

If the computer is interfaced to J4 rather than to the microphone connector of the control head, then data is transferred directly through the interface.

RF INTERFACE

The microprocessor controls what frequencies will be used for receive and transmit. It does so by sending the synthesizer the proper data. Once the data is sent, then the processor will apply a pulse on P3-2 to latch the data and begin operating at the selected frequency. The processor will wait for the synthesizer to lock on the new frequency and then check U701-23 to see if the synthesizer is actually in lock. If it has locked, then P3-5 will be low and U704A (transistor) will be off which makes U701-23 high.

When the radio needs to transmit, the processor will cause U703-6 to be high. This will cause U703-706 to be high, turning Q718 on and making P3-6 low in order to select the transmit VCO. It then brings U701-14 (DPTT) low which enables the transmit power control.

When the RF board detects carrier, it will cause P3-9 to go low, which turns Q717 off. This is read as high by the processor at U701-22. Demodulated audio from the RF board is present at P3-10. It is then routed to the control board filters.

AUDIO POWER AMPLIFIER

The audio signal from the wiper of the volume control is applied through C501 and C502 to the base of Q501. Transistors Q501 and Q502 form a differential input stage. Feedback from the speaker output is applied via R508 to the base of Q502. This feedback signal is also applied to the junction of input capacitors C501 and C502. This configuration allows these two capacitors to function as a two-pole high-pass active filter, with a cutoff frequency of approximately 300 Hz. This filter helps in attenuating "Private-Line" tones and other low-frequency noise below the desired audio passband.

The output of Q503 is direct-coupled to stage Q503. The collector load resistor of Q503 is split, and the speaker output signal is coupled to the junction of the two resistors R509 and R510 via C509. This "bootstrapping" allows increased base drive to Q504 during upward peaks in the audio waveform. This is necessary to allow the output stages to swing as close as possible to the power supply voltage.

STORNOPHONE 5500 THEORY OF OPERATION

The output of Q503 is direct-coupled to the output stages. Each output stage consists of a pair of transistors (Q504/Q506 and Q505/Q507) which are configured as "unity voltage gain collector followers), in which the collector signal of the second transistor is fed back to the emitter of the first transistor. The audio signal from Q503 appears equally at the bases of Q504 and Q505. Diodes CR501 and CR5023 provide thermal tracking of the base-emitter junctions of Q504 and Q505 to maintain constant idle current in Q504 and Q505, regardless of ambient temperature. Resistors R517 and R518 also help maintain constant idle current by eliminating any tendency toward thermal run-away. The output devices are biased just below cutoff, and draw low idle current with no audio input signal. As the audio signal across R512 and R513 increases sufficiently, Q506 and Q507 begin to conduct, supplying the high-current audio signal to the 2 Ohm speaker load coupling capacitor C514.

Transistor Q508 is a switch which electronically turns the audio power amplifier on and off by switching the base bias voltage to Q501 and Q504/Q505. This is used as an audio mute control which mutes the speaker when squelched or in the transmit mode. This is also used to turn the audio PA off when the radio is turned off, since the audio PA circuit does not draw any current when muted in this manner.

Capacitors C505, C506, and C510 through C513 protect against rectification of radio signals produced by the radio's own transmitter or other external sources which may otherwise cause noise in the speaker.

TRANSMITTER AUDIO

Microphone audio from the control head (via J4 pin 10) is applied to mute gate Q601-E. R601 and R602 provide filtered DC to operate the amplifier stages in the microphone.

A "high" at U705 pin 12 saturates U704G (transistor), which biases gate Q601 into saturation, allowing audio to pass. Flat or pre-emphasized audio is selected by JU601 or JU602 respectively. The two R-C networks both provide the same impedance at 1 kHz, therefore the microphone gain at 1 kHz is the same. However, the reactance of C605 varies through the audio range, causing 6 dB/octave pre-emphasis, whereas the reactance of C604 is constant and very low through the same range, causing a flat response.

Operational amplifier U601A provides limiting against the supply and ground rails. Diode CR601 in the supply lead ensures that limiting occurs symmetrically about the 4.8 V reference. The output of U601A, when limiting, is a 7.2 V p-p square wave.

The output of U601A is attenuated 6 dB by a resistive divider, consisting of R611 (upper resistor in divider) and the parallel combination of R612, R613 and R610 (lower resistor). This attenuation prevents the splatter filter U601B from limiting on overshoot peaks.

U601B is a 3-pole active low-pass filter with a -1 dB frequency of approximately 3200 Hz and approximately 1 dB ripple. Additional attenuation is provided by L601 and C608, which form a series L-C trap at 8650 Hz, further reducing adjacent channel splatter components produced by the limiter. The output of U601B is applied to the VCO and reference oscillator circuits on the RF board via P3 pin 1.

Select 5 tones from the Select 5 encoding circuits are applied (via R835, R603 and C603) to the summing input of stage U601A, where they are processed in the same manner as microphone signals. Mute gate Q601 is always cut off during Select 5 tone transmission to prevent voice from interfering with the signalling tones.

In some applications it is necessary to attenuate the Select 5 tone path to allow continuous low-level transmission of an emergency tone while the microphone is simultaneously enabled. The attenuation is accomplished by Q719; when saturated, a resistor divider is formed by R835 which provides approximately 12 dB attenuation.

STORNOPHONE 5500 THEORY OF OPERATION

"Private-Line" (PL) tones are transmitted continuously and therefore are applied after the limiter stage U601A, so that the PL tones are not removed if the limiter is captured by loud voice signals. The tones, generated by the microprocessor and filtered by stage U601C, are applied via resistive divider made of R610 (upper resistor in the divider) and the parallel combination of R611, R612 and R613 (lower resistor). These values are chosen so that PL tone deviation is approximately 10% of full system deviation.

LOW-LEVEL RECEIVER AUDIO STAGES

Detector audio from the RF board is obtained at P3 pin 10 and applied to stage U551A. A resistor on the RF board (R62) adjusts the level of the audio for 12.5 kHz or 20/25 kHz channel spacing systems, so that the level applied to U551A is approximately 18 mV RMS for 60% of full system deviation.

The gain of U551A is adjusted so that limiting occurs (against the supply and ground rails) for audio levels, corresponding to approximately 15% of full system deviation. Diode CR551 in the supply lead of Q551 ensures that limiting is symmetrical about the 4.8 V reference. The limiting action greatly reduces the level of impulse noises, noise due to fading, and squelch tail noise bursts, while having no effect on modulated signals.

The output level of U551A is attenuated by divider R565/R566 before being applied to accessory connector J5 pin 7. Audio at this point is also applied to stage U551B, which is a 3-pole high-pass active filter with a -1 dB point of approximately 300 Hz. This filter removes "PL" tones and noise below 300 Hz.

The output of stage U551B is applied to stage U551C. This stage determines the "flat" or "de-emphasized" receive audio characteristic as selected by jumpers JU551 or JU552 respectively. For flat response, R558 determines the attenuation of this stage, which is the same as the attenuation at 1 kHz due to the reactance of C557 when de-emphasis is selected. However, the reactance of C557 varies through the 300-3000 Hz audio band, providing a 6 dB/octave de-emphasis response.

The output of U551C is applied to mute gate Q551. This gate provides muting of the receiver audio by the microprocessor, based on signals received from the carrier squelch circuits (via Q720), hang-up line status, selective signalling decoders, etc. When U705 pin 11 is "high", U704E is saturated, which biases Q551 into saturation, allowing audio to pass to stage U551D. This stage is a buffer with 10 dB gain which delivers the audio from a low-impedance source to the top of the volume control in the control head.

Audio from U551A is routed to low-pass filter U801A, and then via JU802 to the limiter and tone detection circuits of the microprocessor. This audio is used for decoding low-frequency signalling tones, such as "PL".

Similarly, the audio from U551B, from which low-frequency noise has been filtered, is routed via JU801 to the same limiter and tone detection circuits; this path is used to decode audible signalling tones such as Select 5.

Tones, generated by the Select 5 encoder circuits, are routed via JU805 to the summing input of stage U551D and are then applied to the volume control. They function as sidetones to verify transmission of the Select 5 tones. Sidetones are defeated when JU805 is removed.

Alert tones, generated as a square wave by the microprocessor, are filtered by C812 and applied (via C813, JU803 and R833) to the summing input of stage U551D. Tones, applied in this manner, are controlled by the setting of the volume control. Optionally, with JU803 out and JU804 in, the alert tones are applied to R507 in the audio power amplifier, where they are reproduced at a constant level, regardless of the volume control setting.

STORNOPHONE 5500 THEORY OF OPERATION

WATCHDOG TIMER

The watchdog timer is a circuit that monitors the microprocessor activity. If it sees that the microprocessor is not functioning properly, it will force a reset condition. When the processor is working properly, it will cause U701-10 to change state periodically. These transistors will cause Q901 (SCR) to trigger and discharge C902. If the processor stops toggling U701-10, then C902 will charge and the voltage on U601D-14 will fall enough to cause U601D-12 to go high. This will turn Q902 on and force the processor to enter standby/reset.

When U601D-12 goes high, it causes the voltage in U601D-13 to increase via R907. It also causes C902 to discharge and raise the voltage at U601D-14. When C902 discharges sufficiently, then the voltage at U601D-14 will be high enough to cause U601D-12 to go low again. This will turn Q902 off and allow the processor to come out of standby/reset.

This process will be repeated as long as the processor fails to toggle U701-10.

EMERGENCY

Select 5 radios with an emergency option will have JU710 removed and a normally closed switch installed between J5-9 and ground. The emergency switch will cause transmission of the emergency tones, even when the radio is turned off (at the control head switch). When the emergency switch is pressed, Q704 will turn on and cause the processor (U701) to be interrupted by a low at U701-17. To prevent noise from causing an emergency condition, the processor will read the emergency switch status at U701-17 for a period of time to ensure that it is still pressed. If so, the processor will begin transmitting the emergency data or tone sequence.

	JU710
Emergency Enabled	out
Emergency Disabled	in

Jumper Table

EXTERNAL ALARM

Select 5 radios with the external alarm option enabled will turn on the vehicle's horn or lights when it receives the proper data or tone sequence. This is done by causing U703-14 to go low which turns on transistors Q713 and Q714. An external relay, connected to J5-8, is then enabled which will activate the external indication.

SIDETONES AND ALERT TONES

When JU805 is installed, the mobile operator will hear the Select 5 tones as they are being generated. If JU805 is removed, then the sidetones will be deleted.

Alert tones will be generated at U701-15 when certain conditions exist. An example is when PTT is pressed while the radio is not in the monitor mode. These tones are filtered by R831 and C812. If JU803 is installed, then the amplitude of the tones will depend on the setting of the volume control. If JU804 is installed, the amplitude will be fixed by R834 regardless of the volume control setting.

LOW-TIER CONTROL BOARD

DC DISTRIBUTION

The CQM5500 control board has two regulated voltage sources that provide 5.0 and 9.6 V. The 5 V source supplies power primarily to the microprocessor, the serial latch (U705) and the memory device(s) (U702 and U703). The 5 V supply is always on, even when the radio is turned off, provided that the radio is properly installed (battery voltage is always present on B+). Since CMOS devices are used, the current drain from the 5 V source is negligible when the radio is turned off. The memory chip(s) is NMOS but power is completely turned off to them via Q705 except when they are being accessed during normal radio operation. The 5 V source is also used to power various transistors used for interfacing and buffering purposes.

The 9.6 V source is turned on and off by the microprocessor. It primarily supplies power to the filters, limiters, amplifiers, and RF board via P3-7.

STORNOPHONE 5500 THEORY OF OPERATION

The microprocessor turns this supply off by causing U705-5 (the latch) to go low. This removes power operational amplifier U401 which disables the 9.6 V regulator circuit and transmit power control circuitry.

A 4.8 V source is derived from the 9.6 V source using a resistive divider (R408 and R409) and filter capacitor (C405). This is used to bias various operational amplifiers.

The audio PA output stage is powered by B+. The microprocessor turns off the audio by causing U705-4 to go low which turns off U704F (transistor) and Q508. The biasing of the output transistors is removed and no current is drawn by them.

POWER UP (Initial battery connection)

When the battery is initially connected to the radio, C710 begins charging. While it is charging, the outputs of the serial latch (U705) are tri-state. This guarantees that U705-5 will be pulled high by R772 and Q708 will be turned on. This turns off Q709 to allow the microprocessor to come out of reset (U701-6, 7 will go high). The watchdog timer's output Q902 is also off during this time in order to allow U701-6, 7 to go high.

C902 in the watchdog circuit is discharged (0 volts across it) which places 9.6 V on U601-14. Since U601-13 is about 2.5 V, U601-12 will go low (1.4 V). The divider, formed by R904 and R908, is such that the transistor will be turned off.

U701-7 immediately goes high and the microprocessor comes out of standby. CR703 forces U701-6 (reset) to rise slowly as C707 begins to charge and the oscillator Y701 begins operation. While the voltage at C701-6 is less than about 4 V, all I/O lines of the microprocessor are high impedance. The voltages on U701-8, 9, 10 are all 5 V to cause the microprocessor to enter the proper mode of operation when it comes out of reset. U701-8 is high because Q722 is on which turns off Q801, allowing R830 to pull the voltage high. U701-9 is high because Q701 is off and R745 pulls it high. U701-10 is high due to R707.

Once C707 has charged, the microprocessor comes out of reset and begins executing its operating program. The microprocessor turns off Q722 to enable information to be read on U701-8. It will toggle the clock and data lines via U701-35 and U701-26. The serial data activity will tickle the watchdog timer in order to prevent it from resetting the microprocessor. The clock and data lines are used to write data to the latch (U705) and to read data from the EEPROM(s) (U702 and U703).

After data is written to the latch, a positive-going pulse is generated on U701-33 to enable new data to be written to the latch output. U705-5 will be high in order to enable the 9.6 V supply.

When data is read from the EEPROM, information is sent to the EEPROM via the clock and data lines mentioned above, but data from the EEPROM is read by the microprocessor at U701-9. While writing data, U701-36 is low which turns off Q701 and allows the EEPROM to control the data line.

PL radio: If the memory is faulty or has improper data, then the microprocessor will continuously re-try reading from it.

Some EEPROMs require that JU705 be cut. These EEPROMs use R713 and C705 as part of an RF oscillator. If this type of EEPROM is used then U703-7 should be a sawtooth waveform with a period of about 12 microseconds any time U701-34 is low. U701-34 is used to turn on power to the EEPROM(s) and is low (enabled) when the EEPROM is being accessed. If an EEPROM is being installed for U702, it will use R712 and C704 for its oscillator. U702-7 should have a similar sawtooth waveform under the same conditions as above. SP applications may require JU706 to be installed in order to use the larger EEPROMs..

STORNOPHONE 5500 THEORY OF OPERATION

512 x 8 EEPROMs	in	-

Jumper Table

After the EEPROM memory is read, the control head LEDs will be initialized. If it is a high-tier control head, the LCD display will become active.

The synthesizer will be initialized to the proper channel by sending the information on the clock and data lines. Once the data is sent U701-32 generates a pulse to latch the data.

POWER DOWN

The radio will operate as long as the switch on the control head is on. When it is turned off, U701-16 will go high and the microprocessor will cause the latch (U705-5) to go low, which turns off the 9.6 V supply and allows standby/reset to occur (U701-7, 6 are low).

Q707 will be off when the emergency switch is off. Q708 will be off when the microprocessor turns off the 9.6 V supply. When both transistors (Q707 and Q708) are off, then Q709 will turn on and put the microprocessor into standby/reset. If any one of Q707 or Q708 is on, the microprocessor will not be in standby/reset.

The microprocessor still has power applied to it and it maintains the current status of the radio (channel number, muting mode selected and other operator-selected information). When the radio is turned on by the control head switch then the radio status is restored to what it was before the switch was turned off.

NOTES

When a low-tier control head is used, the channel may be changed even with the switch off but no LED's are on to indicate the change.

If the channel switch is pressed while transmitting (PTT, call, ...) the LED will change but the microprocessor does not set the new channel immediately; this will be done automatically after transmission is completed.

PL RADIO CONTINUOUS MEMORY EXCEPTION

The CS/PL radio will turn off the external audio PA and clear the speaker override function of the handset any time the radio is turned on.

CONTROL HEAD INTERFACE

Two types of control heads may be used. The low-tier control head uses LEDs as the primary way of indicating the radio status. The high-tier control status uses an LCD. Both control heads have momentary switches used for changing the channel and other functions.

Some functions operate the same way, regardless of which type of control head is used. The PTT switch on the microphone controls Q715 via J4-2 and is read at U701-15. The Hang-Up Box (HUB) switch controls Q713 via J4-7 and is read at U701-17. Receive audio is routed to the control head volume control at J4-3.

STORNOPHONE 5500 THEORY OF OPERATION

The volume-dependent audio is returned to the command board at J4-11 and sent to the audio PA. The speaker connections at J4-5 and J4-12 serve the purpose of connecting a speaker to the control head when a remote-mount radio installation is used.

LOW-TIER CONTROL HEAD

When a low-tier control head (parallel control head) is used, the control board will directly control the TX/Busy LED (yellow) via Q703. The channel annunciator LEDs are controlled by the control head logic. The monitor/squelch/reset button and the call button are read directly by the control board. The monitor/squelch/reset button controls the state of Q712 which is read at U701-20.

The call switch (Select 5 models only) is read in a more complex way. A single control line is used to either read the call switch or to control the call LED. To turn on the call LED, Q703 is turned on which brings its output low. To read the switch, Q703 is turned off. This allows the call switch to control Q704 and the microprocessor reads the switch status at U701-22. Thus, if the microprocessor has the call LED on, it must briefly turn it off to read the call switch. Logic on the control head is used to indicate if channel 1 or 2 is selected. The channel information is sent to U701-13 via Q710.

HIGH-TIER CONTROL HEAD

The control board communicates to the high-tier control head (serial control board) over a 2-wire asynchronous data link (Q710, J4-8 and Q711, J4-15). Please note that this serial link is different from the synchronous serial bus, used to control the serial latch, EEPROMs and synthesizer. The control head has a microprocessor in it that processes button presses, LED display, and LCD display. The command board microprocessor resets the control head microprocessor via Q702 at power-up or if communication between the two processors fails. Using a serial data protocol, information is exchanged between the processors to update the display or change the current status of the radio. Asynchronous 7-bit data with odd parity is sent at 1200 baud in a half-duplex manner (the control head processor is simplex and the control board processor is duplex). J4-1 is a spare line and is not used.

PROGRAMMING MODE

When the radio needs to be customized for a particular customer's channel and other radio information, a computer is connected to the radio and the data is programmed into the EEPROMs. The computer may be interfaced directly to J4, or it may be connected to the radio through the microphone connector. In either case, the special programming mode is entered by raising the voltage on the HUB line (J4-7) to at least 5 V. This will cause Q714 to turn off and generate a non-maskable interrupt to the microprocessor. The microprocessor will stay in the programming mode as long as U701-4 (NMI) is low. Since the microprocessor cannot read the state of U701-8 directly, it reads it at U701-15 via R774.

When the processor sees a high at U701-14 it will exit the programming mode and begin normal operation. This allows recovery in case noise caused the programming mode to appear active momentarily.

PROGRAMMING MODE, LOW-TIER CONTROL HEAD

If a low-tier control head is connected during the programming mode, the data from the computer is sent on the PTT pin of the microphone connector to J4-2 where it controls Q715 which is the microprocessor's serial data input.

STORNOPHONE 5500 THEORY OF OPERATION

Data from the microprocessor is sent to the computer at U701-12 (its serial data output) to Q711. JU704 must be installed for the data to go to the microphone audio pin of the microphone connector.

Control Head	JU701	JU702	JU703	JU704
Low-Tier	out	in	out	in
High-Tier	in	out	in	out

Jumper Table

PROGRAMMING MODE, HIGH-TIER CONTROL HEAD

If a high-tier control head is connected during the programming mode, the situation is very different from the low-tier control head operation. The reason for this is that the normal (not programming mode) operation of the radio requires that the microprocessor serial data input and output be routed to J4-8 and J4-15 in order to communicate with the control head serially. If PTT and microphone audio were also connected to the data lines, then the radio could not function properly. In order to solve this problem, the high-tier control head processor will rapidly read the PTT line and echo the information to J4-8 to get the data from the computer to the control board. Likewise, data from the control board at J4-15 will be rapidly read and echoed to the microphone audio pin of the microphone connector. Note that this control head operation is true only when it senses that the programming mode is active.

Control Head	JU701	JU702	JU703	JU704
Low-Tier	out	in	out	in
High-Tier	in	out	in	out

Jumper Table

RF INTERFACE

The microprocessor controls what frequencies will be used for receive and transmit. It does so by sending the synthesizer the proper data. Once the data is sent, then the processor will apply a pulse on P3-2 to latch the data and begin operating at the selected frequency. The processor will wait for the synthesizer to lock on the new frequency and then check U701-19 to see if the synthesizer is actually in lock. If it has locked, then P3-5 will be low and U704A (transistor) will be off which makes U701-19 high.

When the radio needs to transmit, the processor will cause U705-6 to be high. This will cause U705-6 to be high, turning Q721 on and making P3-6 low in order to select the transmit VCO. It then brings U701-37 low which enables the transmit power control.

When the RF board detects carrier, it will cause P3-9 to go low, which turns Q720 off. This is read as high by the processor at U701-18. Demodulated audio from the RF board is present at P3-10. It is then routed to the control board filters.

STORNOPHONE 5500 THEORY OF OPERATION

AUDIO POWER AMPLIFIER

The audio signal from the wiper of the volume control is applied through C501 and C502 to the base of Q501. Transistors Q501 and Q502 form a differential input stage. Feedback from the speaker output is applied via R508 to the base of Q502. This feedback signal is also applied to the junction of input capacitors C501 and C502. This configuration allows these two capacitors to function as a two-pole high-pass active filter, with a cutoff frequency of approximately 300 Hz. This filter helps in attenuating "Private-Line" tones and other low-frequency noise below the desired audio passband.

The output of Q501 is direct-coupled to stage Q503. The collector load resistor of Q503 is split, and the speaker output signal is coupled to the junction of the two resistors R509 and R510 via C509. This "bootstrapping" allows increased base drive to Q504 during upward peaks in the audio waveform. This is necessary to allow the output stage to swing as close as possible to the power supply voltage.

The output of Q503 is direct-coupled to the output stages. Each output stage consists of a pair of transistors (Q504/Q506 and Q505/Q507) which are configured as "unity voltage gain collector followers", in which the collector signal of the second transistor is fed back to the emitter of the first transistor. The audio signal from Q503 appears equally at the bases of Q504 and Q505. Diodes CR501 and CR5023 provide thermal tracking of the base-emitter junctions of Q504 and Q505 to maintain constant idle current by eliminating any tendency toward thermal run-away. The output devices are biased just below cutoff, and draw low idle current with no audio input signal. As the audio signal across R512 and R513 increases sufficiently, Q506 and Q507 begin to conduct, supplying the high-current audio signal to the 2 Ohm speaker load coupling capacitor C514.

Transistor Q508 is a switch which electronically turns the audio power amplifier on and off by switching the base bias voltage to Q501 and Q504/Q505. This is used as an audio mute control which mutes the speaker when squelched or in the transmit mode. This is also used to turn the radio PA off when the radio is turned off, since the audio PA circuit does not draw any current when muted in this manner.

Capacitors C505, C506, and C510 through C513 protect against rectification of radio signals produced by the radio's own transmitter or other external sources which may otherwise cause noise in the speaker.

TRANSMITTER AUDIO

Microphone audio from the control head (via J4 pin 10) is applied to mute gate Q601-E. R601 and R602 provide filtered DC to operate the amplifier stages in the microphone.

A "high" at U705 pin 12 saturates U704G (transistor), which biases gate Q601 into saturation, allowing audio to pass. Flat or pre-emphasized audio is selected by JU601 or JU602 respectively. The two R-C networks both provide the same impedance at 1 kHz, therefore the microphone gain at 1 kHz is the same. However, the reactance of C605 varies through the audio range, causing 6 dB/octave pre-emphasis, whereas the reactance of C604 is constant and very low through the same range, causing a flat response.

Operational amplifier U601A provides limiting against the supply and ground rails. Diode CR601 in the supply lead ensures that limiting occurs symmetrically about the 4.8 V reference. The output of U601A, when limiting, is a 7.2 V p-p square wave.

The output of U601A is attenuated 6 dB by a resistive divider, consisting of R611 (upper resistor in divider) and the parallel combination of R612, R613 and R610 (lower resistor). This attenuation prevents the splatter filter U601B from limiting on overshoot peaks.

STORNOPHONE 5500 THEORY OF OPERATION

U601B is a 3-pole active low-pass filter with a -1 dB frequency of approximately 3200 Hz and approximately 1 dB ripple. Additional attenuation is provided by L601 and C608, which form a series L-C trap at 8650 Hz, further reducing adjacent channel splatter components produced by the limiter. The output of U601B is applied to the VCO and reference oscillator circuits on the RF board via P3 pin 1.

Select 5 tones from the Select 5 encoding circuits are applied (via R835, R603 and C603) to the summing input of stage U601A, where they are processed in the same manner as microphone signals. Mute gate Q601 is always cut off during Select 5 tone transmission to prevent voice from interfering with the signalling tones.

In some applications it is necessary to attenuate the Select 5 tone path to allow continuous low-level transmission of an emergency tone while the microphone is simultaneously enabled. The attenuation is accomplished by Q719; when saturated, a resistor divider is formed by R835 which provides approximately 12 dB attenuation.

"Private-Line" (PL) tones are transmitted continuously and therefore are applied after the limiter stage U601A, so that the PL tones are not removed if the limiter is captured by loud voice signals. The tones, generated by the microprocessor and filtered by stage U601C, are applied via resistive divider made of R610 (upper resistor in the divider) and the parallel combination of R611, R612 and R613 (lower resistor). These values are chosen so that PL tone deviation is approximately 10% of full system deviation.

LOW-LEVEL RECEIVER AUDIO STAGES

Detector audio from the RF board is obtained at P3 pin 10 and applied to stage U551A. A resistor on the RF board (R62) adjusts the level of the audio for 12.5 kHz or 20/25 kHz channel spacing systems, so that the level applied to U551A is approximately 18 mV RMS for 60% of full system deviation. The gain of U551A is adjusted so that limiting occurs (against the supply and ground rails) for audio levels, corresponding to approximately 15% of full system deviation. Diode CR551 in the supply lead of Q551 ensures that limiting is symmetrical about the 4.8 V reference. The limiting action greatly reduces the level of impulse noises, noise due to fading, and squelch tail noise bursts, while having no effect on modulated signals.

The output level of U551A is attenuated by divider R565/R566 before being applied to accessory connector J5 pin 7. Audio at this point is also applied to stage U551B, which is a 3-pole high-pass active filter with a -1 dB point of approximately 300 Hz. This filter removes "PL" tones and noise below 300 Hz.

The output of stage U551B is applied to stage U551C. This stage determines the "flat" or "de-emphasized" receive audio characteristic as selected by jumpers JU551 or JU552 respectively. For flat response, R558 determines the attenuation of this stage, which is the same as the attenuation at 1 kHz due to the reactance of C557 when de-emphasis is selected. However, the reactance of C557 varies through the 300-3000 Hz audio band, providing a 6 dB/octave de-emphasis response.

The output of U551C is applied to mute gate Q551. This gate provides muting of the receiver audio by the microprocessor, based on signals received from the carrier squelch circuits (via Q720), hang-up line status, selective signalling decoders, etc. When U705 pin 11 is "high", U704E is saturated, which biases Q551 into saturation, allowing audio to pass to stage U551D. This stage is a buffer with 10 dB gain which delivers the audio from a low-impedance source to the top of the volume control in the control head.

Audio from U551A is routed to low-pass filter U801A, and then via JU802 to the limiter and tone detection circuits of the microprocessor. This audio is used for decoding low-frequency signalling tones, such as "PL".

STORNOPHONE 5500 THEORY OF OPERATION

Similarly, the audio from U551B, from which low-frequency noise has been filtered, is routed via JU801 to the same limiter and tone detection circuits; this path is used to decode audible signalling tones such as Select 5.

Tones, generated by the Select 5 encoder circuits, are routed via JU805 to the summing input of stage U551D and are then applied to the volume control. They function as sidetones to verify transmission of the Select 5 tones. Sidetones are defeated when JU805 is removed.

Alert tones, generated as a square wave by the microprocessor, are filtered by C812 and applied (via C813, JU803 and R833) to the summing input of stage U551D. Tones, applied in this manner, are controlled by the setting of the volume control. Optionally, with JU803 out and JU804 in, the alert tones are applied to R507 in the audio power amplifier, where they are reproduced at a constant level, regardless of the volume control setting.

WATCHDOG TIMER

The watchdog timer is a circuit that monitors the microprocessor activity. If it sees that the microprocessor is not functioning properly, it will force a reset condition. When the processor is working properly, it will cause U701-36 to change state periodically. These transistors will cause Q901 (SCR) to trigger and discharge C902. If the processor stops toggling U701-36, then C902 will charge and the voltage on U601D-14 will fall enough to cause U601D-12 to go high. This will turn Q902 on and force the processor to enter standby/reset.

When U601D-12 goes high, it causes the voltage in U601D-13 to increase via R907 and C902 to discharge and raise the voltage at U601D-14. When C902 discharges sufficiently, then the voltage at U601D-14 will be high enough to cause U601D-12 to go low again. This will turn Q902 off and allow the processor to come out of standby/reset. This will be repeated as long as the processor fails to toggle U701-10.

EMERGENCY

Select 5 radios with an emergency option will have JU710 removed and a normally closed switch installed between J5-9 and ground. The radio must be turned on and functioning before the emergency switch will cause transmission of the emergency tones.

When the emergency switch is pressed, Q706 will turn on and cause the processor (U701) to be interrupted by a low at U701-39. To prevent noise from causing an emergency condition, the processor will read the emergency switch status at U701-22 for a period of time to ensure that it is still pressed. In order to read the emergency switch, the processor will first cause U701-10 to go high, which causes Q703 to turn on and Q704 to turn off. When the switch has been pressed long enough, the processor will begin transmitting the emergency tone sequence.

	JU710
Emergency Enabled	out
Emergency Disabled	in

Jumper Table

EXTERNAL ALARM

Select 5 radios with the external alarm option enabled will turn on the vehicle's horn or lights when it receives the proper tone sequence. This is done by causing U705-14 to go low which turns Q716 and Q717 on. An external relay, connected to J5-8, is then enabled which will activate the external indication.

STORNOPHONE 5500 THEORY OF OPERATION

EXTERNAL PA

PL radios with the external PA option enabled will route audio to an external speaker/amplifier when PL is decoded and the PA is enabled by pressing a button on the high-tier control head. The external PA is enabled in the same way the external alarm is enabled in Select 5 radios. Audio is then routed to the external PA at J5-7 (buffered receive audio).

SIDETONES AND ALERT TONES

Select 5 radios will generate sidetones so the mobile operator can hear the Select 5 tones as they are being transmitted. If JU805 is removed, then the sidetones will be deleted.

Both PL and Select 5 radios will generate alert tones at U701-14 when certain conditions exist. An example is when PTT is pressed while the radio is not in the monitor mode. These tones are filtered by R831 and C812. If JU803 is installed, then the amplitude of the tones depends on the setting of the volume control.

If JU804 is installed, the level will be fixed by R834, regardless of the volume setting.

	JU803	JU804	JU805
Volume Control Dependent Alert Tones	in	out	-
Fixed Level Alert Tones	out	in	-
Select 5 Sidetone Enable	-	-	in
Select 5 Sidetone Disable	-	-	out

Jumper Table

Error tones are generated by the control board. Major alert (key pressing during PTT) is generated by the control head. Key feedback on the high-tier control head is generated by the control head.

STATIC PROTECTION

VR651, VR652, VR653, VR654, VR655, VR656, and VR657 are Zener diodes which protect the radio circuitry from static electricity that may enter on the radio connectors.

TEST PADS

Not used.

TRANSMITTER POWER CONTROL

When the microprocessor switches the radio from receive to transmit, the 9.6 V source is turned on via Q403. This supplies power to part of the RF power amplifier stage.

The exciter A + source is enabled when transmitting as long as the synthesizer is in lock (P3-5 is low). When the transmitter is not in lock, U704D (transistor) will turn on and inhibit the A +.

STORNOPHONE 5500 THEORY OF OPERATION

The voltage at P6-4 is used to control the RF power output. As the voltage increases, the output power increases. A significant variation of this voltage will be seen between a channel that is programmed for low power and a channel that is programmed for high power. Potentiometers R453 and R455 will control the actual voltage, measured for high and low power respectively.

U705-7 will be high when low power is selected and low when high power is selected. This controls Q453 and varies the bias at U401B.

CHAPTER
CHAPITRE
KAPITEL

4

ALIGNMENT

STORNOPHONE 5500, 136 - 174 MHz

NOTE

Key the radio while making adjustments or measurements.

GENERAL

Perform all adjustments at a supply voltage of 13.2 ± 0.1 VDC, unless the instructions call for a different voltage.

Interpret instructions to turn controls clockwise (CW) or counterclockwise (CCW) to mean "as viewed from the component side of the circuit board."

The locations of the adjustable components are shown at the back of this chapter.

When you perform any of the tune-up procedures given in the following sections, the radio must be completely assembled except for the chassis cover, the top cover of the synthesizer compartment, and the radio sleeve. When you have completed the tune-up, install the synthesizer cover, chassis cover, and sleeve before testing the radio against specifications.

The following test equipment is recommended for aligning and servicing the CQM5500 radio:

RECOMMENDED TEST EQUIPMENT:

R2001	Communication System Analyzer or
R2200	Service Monitor
GTF180	Mobile Test Set with
GTF244	Adapter Cable for CQM5500
PFT4053	Psophometric Filter
FTP3005	Select 5 Test Unit (not required with R2001)
R1011	Power Supply or
S1347	Power Supply (for radios with 10 W or less power)
R1037	Digital Multimeter or
R1024	Digital Multimeter

TRANSMITTER ADJUSTMENT

1. Preset the following pots:

HI PWR	R453	Fully CCW
LO PWR	R455	Fully CCW
VOLT LIMIT	R463	Fully CW

ALIGNMENT 136 - 174 MHz, STORNOPHONE 5500

2. Adjust the radio's DC supply voltage to 13.2 ± 0.1 VDC (12.6 VDC for MAU1, 6 Watt models).
3. Select the channel with the highest transmit frequency.
4. Connect the radio antenna output to an accurate RF power meter that provides a 50 ohm load.
5. Connect a DC voltmeter from the steering line test point (SL) to ground. Meter impedance should be 11 megohms or more.
6. Key the radio and adjust coil L210 until the voltmeter reads 7.0 VDC
7. Select the channel with the lowest transmit frequency. Key the radio and verify that the DC voltage is at least 2.5 VDC
8. Select any transmit channel. (If the radio has the MAB889 slaved RF power option, select any high-power transmit channel.)
9. Key the radio and adjust R453 (HI PWR) for:

Model Number	Power Setting
MAU0	1.0 W
MAU1	6.0 W
MAU2	10.0 W
MAU3	25.0 W

10. Switch through all channels (all high-power channels for MAB889). On each channel, key the radio and note the power output. For MAU0, MAU2, and MAU3 models, note the channel that gives the minimum power output; for MAU1 models note the channel that gives the maximum power output. If more than one channel gives the same maximum or minimum power, choose any one of those channels.
11. Switch through all transmit channels (all high-power channels for MAB889). On each channel, key the radio while watching the DC voltage at Pin 4 of connector P6, or at test point CV on the command board. Record the number of the channel that gives the greatest voltage, and what that voltage is. (If more than one channel gives the same maximum voltage, choose any one of those channels.) If it is greater than 10.0 VDC go to Step 14. If not, go to Step 12.
12. On the channel that Step 11 showed to have the highest DC voltage, turn R463, fully CCW. Turn R453 fully CW.
13. Key the radio. Adjust the voltage limit pot, R463, for a DC voltage 2.0 V higher than the voltage level recorded in Step 11, as measured at pin 4 of P6 or at test point CV.
14. Set the channel selector to the channel that was noted in Step 10. Key the radio and adjust R453, for:

Model Number	Power Setting
MAU0	1.1 W
MAU1	5.6 W
MAU2	10.7 W
MAU3	26.8 W

15. Verify that all channels (all high-power channels in MAB889) produce at least 1.0, 10.0, or 25.0 W, as appropriate, for MAU0, MAU2, and MAU3 models. Verify that no channel produces more than 6.0 W for MAU1 models.

ALIGNMENT 136 - 174 MHz, STORNOPHONE 5500

16. If the radio has Option MAB889 (slaved RF power level), select any low-power channel. Key the radio and adjust R455 for an output power of 1.0 W (or other specified power setting) for MAU1 and MAU2 models. Verify that the RF power output on all low-power channels is between 0.7 and 1.4 W. Readjust R455 slightly if necessary. For MAU0 models, adjust R455, for an output power of 0.1 W or some other specified power level. Verify that the RF power output on all low-power channels is between 70 and 140 mW.

REFERENCE OSCILLATOR ADJUSTMENT

1. Connect the radio antenna output to an accurate frequency counter through a suitable attenuator.
2. Select any transmit channel.
3. Key the radio and adjust L151 (all models except those with 2 ppm stability) or R163 (models with 2 ppm stability) until the exact transmit frequency (± 100 Hz) appears on the counter.
4. Check all transmit channels to verify that the correct transmit frequencies have been programmed.

DEVIATION ADJUSTMENT

1. Connect the radio antenna output to a modulation analyzer or test receiver through a suitable attenuator.
2. Connect an audio oscillator to the microphone audio input through the circuit shown in Figure 1. Set the oscillator frequency to 1 kHz and the output level to 800 mV RMS.

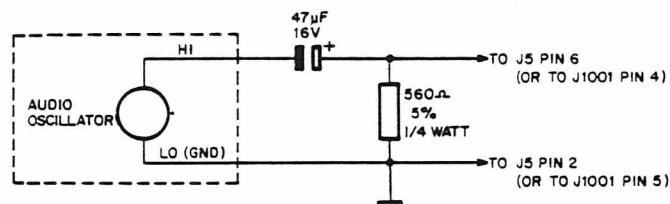

Figure 1
Connection of audio oscillator to the microphone input

ALIGNMENT 136 - 174 MHz, STORNOPHONE 5500

3. Preset pots R302 (VCO MOD) and R305 (REF MOD) fully CCW.
4. Select any transmit channel. For PL models select any channel that transmits PL.
5. Key the radio and adjust the VCO MOD pot, R302, for the appropriate deviation level:

Channel Spacing	Deviation Setting
25 kHz	± 4.6 kHz
20 kHz	± 3.7 kHz
12.5 kHz	± 2.3 kHz

NOTE

If + and - deviation readings differ, use only the higher reading.

6. For 25 kHz channel spacing models only, the procedure is complete. For others, continue with Step 7.
7. Change the audio oscillator frequency to 200 Hz, and maintain the output level at 800 mV RMS.
8. Key the radio and observe the waveform on an oscilloscope connected to the demodulated output of a test receiver. The test receiver should be non-deemphasized, and there must be DC coupling between the test receiver and the scope. (AC Coupling is suitable if the corner frequency is 2 Hz or lower.) Adjust R305 (REF MOD) for the flattest square-wave response with minimum tilt.
9. Return the audio oscillator frequency to 1 kHz, 800 mV RMS, and repeat Step 5.

RECEIVER ADJUSTMENT

NOTE

Adjust the transmitter VCO and reference oscillator (see the section: TRANSMITTER ADJUSTMENT) before aligning the receiver.

RECEIVER VCO

1. Connect a high-impedance (11 megohms or greater) DC voltmeter from the steering line test point (SL) to ground.
2. (Radios with more than one receive frequency) Select the channel with the lowest frequency.
3. Adjust Capacitor C201 until the voltmeter reads 7.0 VDC

RECEIVER

1. Find the tune-up frequency, f_{tune} , as follows:

- a) On single-channel radios and multi-channel radios with a single receive frequency:

$$f_{\text{tune}} = f_{\text{receive}}$$

- b) On multi-channel radios that have a receive bandwidth of 2 MHz or less:

$$f_{\text{tune}} = \text{frequency of highest-frequency channel}$$

- c) On multi-channel radios that have a receive bandwidth greater than 2 MHz but less than or equal to 4 MHz, find f_{mid} , where:

$$f_{\text{mid}} = (f_{\text{highest}} + f_{\text{lowest}}) : 2$$

If one of the radio's channels has a frequency within 500 kHz of f_{mid} , perform the tune-up on that channel. If not, you must either get a tune-up PROM programmed to f_{mid} , or program the tune-up frequency, f_{mid} , into the radio (EZ models only). EV models contain a preprogrammed tune-up channel, accessed by temporarily shorting the TEST pins on the command board.

2. Set the channel selector switch to the channel of the tune-up frequency as determined in Step 1, above.
3. Connect a 2 ohm resistive load across Pin 4 of J5 (hot head) and Pin 5 of J5 (ground lead). Monitor the audio output across this load resistor.
4. Preset the slugs of L1 through L7 for f_{tune} flush with the circuit board.
5. Connect a DC voltmeter from the local oscillator test point (L0) to ground.
6. Peak the injection filter coils, L6, L5, and L7, in that order, for a maximum DC voltage, typically between 2.1 and 3.5 VDC. Repeat until you cannot make the DC voltage increase any farther.
7. Connect an RF signal generator to the antenna connector and adjust it to generate an unmodulated on-channel signal strong enough to quiet the receiver.
8. Connect an AC voltmeter with bandwidth of at least 500 kHz (an HP331A distortion analyzer, for example) from the IF test point to ground. Increase the RF generator output until the AC voltmeter indicates approximately 30 mV. Adjust the RF filter coils L1, L3, L4, and L5 until the voltmeter peaks. Reduce the generator's RF level as necessary to maintain approximately 30 mV RMS on the meter during this process. Repeat the adjustment until you can get no further increase in voltage.
9. Set the RF level of the generator to 1 mV. Modulate it with a 1 kHz tone at 60% of full system deviation. Full system deviation for a channel spacing of 25 kHz is ± 5 kHz; for 20 kHz ± 4 kHz; for 12.5 kHz ± 2.5 kHz. Adjust the volume control to get an audio level of about 1 Volt RMS across the 2 ohm load. Slowly peak the quad coil, L54 for maximum audio output.
10. Adjust the squelch as follows:
 - a) Preset the squech control R59, fully CCW.
 - b) Apply an on-channel RF signal at a level of 1 mV. Modulate with a 1 kHz tone at 60% of full system deviation.

ALIGNMENT 136 - 174 MHz, STORNOPHONE 5500

- c) Adjust the volume control for 1.7 V RMS across the 2 ohm load.
- d) Reduce the RF level until the CCITT-weighted SINAD is 10 dB.
- e) Enable the carrier-squelch mode with the front panel switch.
- f) Slowly turn the squelch control CW until the audio is squelched (muted), then very slowly turn CCW until the radio just unsquelches (unmutes).
- g) Reduce the generator RF level to zero, slowly increase the level until the radio just unsquelches, and verify that the CCITT-weighted SINAD at this RF level is between 8 and 12 dB SINAD. Readjust R59 slightly if necessary.

ABGLEICHANLEITUNG

STORNOPHONE 5500, 136 - 174 MHz

ACHTUNG

Den Sender nur beim Abgleichen oder zur Durchführung von Messungen tasten!

ALLGEMEINES

Wenn nicht anders angegeben sind alle Messungen bei einer Versorgungsspannung von $13,2 \text{ V} \pm 0,1 \text{ V}$ durchzuführen. Den Sender nur beim Abgleichen oder zur Durchführung von Messungen tasten. Anweisungen, einen Regler rechtsherum (im Uhrzeigersinn) oder linksherum (entgegen dem Uhrzeigersinn) zu drehen, sind bei Ansicht von der Bestückungsseite zu verstehen. Die Lage der Abgleichpunkte ist hinten im Kapitel abgebildet.

Beim Abgleich gemäß den folgenden Abschnitten muß das Gerät bis auf das Chassis und die Abschirmbleche des Chassis und des Synthesizers zusammengebaut sein. Alle Teile müssen sich allerdings wieder an vorgesehener Stelle befinden, wenn das Gerät nach dem Abgleich zur Überprüfung seiner Daten gemessen wird.

EMPFOHLENE MEßGERÄTE

R2001	Funk-System-Meßplatz, oder
R2200	Service-Monitor
GTF180	Prüfgerät für Mobilgeräte mit
GTF244	Adapterkabel für CQM5500
PFT4053	Psophometrisches Filter
FTP3005	Fünfton-Prüfgerät (bei Verwendung des R2001 nicht erforderlich)
R1011	Netzteil, oder
S1347	Netzteil für Funkgeräte mit niedriger HF-Ausgangsleistung (unter 10 W)
R1037	Digitales Multimeter, oder
R1024	Digitales Multimeter

SENDERABGLEICH

1. Voreinstellungen:
 - * R453 (HI PWR) an den linken Anschlag
 - * R455 (LO PWR) an den linken Anschlag
 - * R463 (VOLT LIMIT) an den rechten Anschlag
2. Die Stromversorgung auf $13,2 \text{ V} \pm 0,1 \text{ V}$ einstellen (bzw. auf 12,6 V bei 6 W Modellen der Modellreihe MAU1).

ABGLEICHANLEITUNG 136 - 174 MHz, STORNOPHONE 5500

3. Den Kanal mit der höchsten Sendefrequenz einstellen.
4. Am Sender ein genaues HF-Wattmeter (mit 50 Ohm Anschluß) anschließen.
5. Ein Gleichspannungsvoltmeter mit mindestens 11 MegOhm Eingangsimpedanz zwischen dem Prüfpunkt der Steuerleitung (SL) und Masse anschließen.
6. Den Sender tasten und Spule L210 abgleichen bis am Voltmeter eine Anzeige von 7,0 V erfolgt.
7. Den Kanal mit der niedrigsten Sendefrequenz wählen, den Sender tasten und sicherstellen, daß die Prüfspannung mindestens 2,5 V beträgt.
8. Irgendeinen Sendekanal einstellen (bei der Option MAB899 "Kanalabhängige HF-Ausgangsleistung" ist ein Kanal mit hoher HF-Leistung einzustellen).
9. Den Sender tasten und die HF-Ausgangsleistung mit dem Potentiometer R453 (HI PWR) auf folgende Werte einstellen:

Modell	HF-Leistung
MAU0	1,0 W
MAU1	6,0 W
MAU2	10,0 W
MAU3	25,0 W

10. Die Sendeleistung aller Kanäle (alle Kanäle mit hoher HF-Leistung bei MAB889) überprüfen und notieren. Bei den Modellen MAU0, MAU2 und MAU3 den Kanal mit der niedrigsten HF-Ausgangsleistung ermitteln. Werden mehrere Kanäle mit gleicher Maximal- bzw. Minimal-Leistung gefunden, ist auf einen dieser Kanäle zu schalten.
11. Auf allen Sendekanälen (bei der Option MAB889 auf allen Sendekanälen mit hoher HF-Leistung) beim Tasten des Senders die Prüfspannung am Anschluß 4 des Steckverbinder P6 (oder am Prüfpunkt CV der Logikplatine) ermitteln. Die Kanalnummer des ermittelten Kanals samt dazugehöriger Prüfspannung notieren. Werden mehrere Kanäle mit gleicher Maximalanzeige gefunden, so ist auf einen dieser Kanäle zu schalten. Wenn diese Spannung mehr als 10 V beträgt ist mit Schritt 14 fortzufahren, sonst fahre man mit Schritt 12 fort.
12. Den bei Schritt 11 ermittelten Kanal mit der Höchsten Prüfspannung einschalten und das Spannungsbegrenzungspotentiometer R463 (VOLT LIMIT) an den linken Anschlag sowie das Potentiometer R453 (HI PWR) an den rechten Anschlag drehen.
13. Den Sender tasten und mit dem Spannungsbegrenzungspotentiometer R463 (VOLT LIMIT) die in Schritt 11 ermittelte Prüfspannung (an P6-4 bzw. Prüfpunkt CV gemessen) um 2,0 V erhöhen.
14. Den bei Schritt 10 ermittelten Kanal einstellen, den Sender tasten und mit dem Potentiometer R453 (HI PWR) die folgenden Werte der HF-Ausgangsleistung einstellen:

Modell	HF-Leistung
MAU0	1,1 W
MAU1	5,6 W
MAU2	10,7 W
MAU3	26,8 W

15. Sicherstellen, daß alle Kanäle (alle Kanäle hoher Leistung bei der Option MAB889) die geforderte HF-Leistung von 1 W (MAU0), 10 W (MAU2) bzw. 25 W (MAU3) aufweisen. Beim Modell MAU1 darf die HF-Ausgangsleistung der einzelnen Kanäle einen Wert von 6,0 W nicht überschreiten.

ABGLEICHCHANLEITUNG 136 - 174 MHz, STORNOPHONE 5500

16. Bei Geräten mit der Option MAB889 (Kanalabhängiger HF-Ausgangsleistung) ist ein Kanal mit niedriger Ausgangsleistung einzustellen. Dann den Sender tasten und bei MAU1- und MAU2-Modellen mit dem Potentiometer R455 (LO PWR) eine Ausgangsleistung von 1 W (Bzw. die geforderte HF-Ausgangsleistung) einstellen. Sicherstellen, daß die Ausgangsleistung 0,7 bzw. 1,4 W beträgt, ggf. R455 geringfügig nachjustieren. Bei MAU0-Modellen ist an diesem Regler eine Leistung von 100 mW (oder die geforderte HF-Ausgangsleistung) einzustellen, die zwischen 70 und 140 mW variieren darf.

ABGLEICH DES REFERENZOSZILLATORS

1. Die Antennenbuchse über einen geeigneten Abschwächer mit einem genauen Frequenzzähler verbinden.
2. Einen beliebigen Sendekanal einstellen.
3. Den Sender tasten und L151 (oder, bei 2 ppm-Geräten, R163) auf genauer Sendefrequenz ± 100 Hz abgleichen.
4. Die Trägerfrequenzen aller Sendekanäle überprüfen und sicherstellen, daß sie dem Programm entsprechen.

HUBEINSTELLUNG

1. Die Antennenbuchse über einen geeigneten Abschwächer mit einem genauen Hubmeter verbinden.
2. An die Mikrofonbuchse wird ein NF-Generator angeschlossen, wie in Abbildung 1 gezeigt. Der Generator soll eine Tonfrequenz von 1000 Hz bei einer Amplitude von 800 mV eff. abgeben.

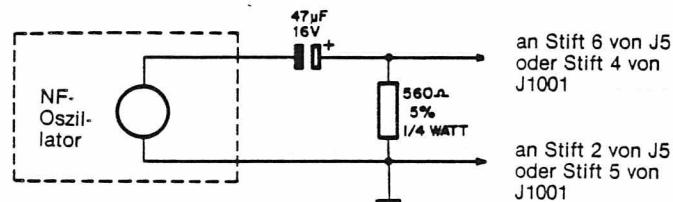

Abbildung 1
Einspeisung eines NF-Signals in die Mikrofonbuchse

3. Die Modulationssteller R302 (VCO MOD) und R305 (REF MOD) an den linken Anschlag drehen.
4. Einen beliebigen Sendekanal einstellen. Bei "Private-Line"-Geräten ist ein Kanal mit "PL"-Modulation zu wählen.

ABGLEICHANLEITUNG 136 - 174 MHz, STORNOPHONE 5500

5. Den Sender tasten und mit dem Poti R302 (VCO MOD) den Hub wie folgt einstellen:

± 4,6 kHz bei 25 kHz Kanalabstand
± 3,7 kHz bei 20 kHz Kanalabstand
± 2,3 kHz bei 12,5 kHz Kanalabstand

HINWEIS

Bei asymmetrischem Hub ist nur die höhere Anzeige zu bewerten.

6. Bei Geräten für 25 kHz Kanalabstand ist die Voleinstellung jetzt beendet. Für die Geräte mit 20 und 12,5 kHz Kanalabstand ist mit Schritt 7 fortzufahren.
7. Den NF-Generator auf 200 Hz justieren. Der Ausgangspegel bleibt auf 800 mV eff. eingestellt.
8. Der Oszillograph muß an den Demodulator-Ausgang des Hubmessers angeschlossen sein. Dieser Ausgang darf keine De-Emphasis aufweisen und muß gleichstromgekoppelt sein (Wechselspannungskopplung ist erlaubt, wenn die Eckfrequenz maximal 2 Hz beträgt). Den Sender tasten und das demodulierte Signal am Oszillographen beobachten. Mit Hilfe des Reglers R305 (REF MOD) ein möglichst flaches Rechtecksignal mit minimaler Neigung einzustellen.
9. Am NF-Generator wieder eine Tonfrequenz von 1 kHz bei einer Amplitude von 800 mV eff. einstellen und Schritt 5 wiederholen.

EMPFÄNGERABGLEICH

HINWEIS

Der Empfänger darf erst nach dem Abgleich des VCO und des Referenzoszillators (siehe SENDERABGLEICH) abgeglichen werden.

EMPFÄNGER-VCO

1. Ein Gleichspannungsvoltmeter mit mindestens 11 MegOhm Impedanz an Prüfpunkt SL anschließen.
2. Bei Mehrkanalgeräten den Kanal mit der niedrigsten Empfangsfrequenz einstellen.
3. Die VCO-Spule des Empfängers (L201) abgleichen, bis eine Spannung von 7,0 V abgelesen wird.

EMPFÄNGER

1. Die Abgleichsfrequenz wie folgt ermitteln:
 - a) Bei Einkanalgeräten und Vielkanalgeräten mit einer Empfangsfrequenz ist dies die Betriebsfrequenz des Empfängers
 - b) Bei Mehrkanalgeräten mit einer Schaltbandbreite von weniger als 2 MHz ist dies die höchste Empfangsfrequenz.

ABGLEICHANLEITUNG 136 - 174 MHz, STORNOPHONE 5500

- c) Bei Mehrkanalgeräten mit einer Schaltbandbreite zwischen 2 und 4 MHz wird die Mittenfrequenz F_m gefunden, indem die höchste (F_h) und tiefste (F_t) Betriebsfrequenzen addiert und dann durch zwei geteilt werden:

$$F_m = (F_h + F_t) : 2$$

Auf dieser Mittenfrequenz ± 500 kHz wird abgeglichen, wenn ein Betriebskanal in diese Toleranz fällt; sonst muß eine Abgleichfrequenz = F_m programmiert werden (gilt nur für EZ-Typen).

2. Den Kanal mit der Abgleichfrequenz (wie in Schritt 1 ermittelt) einstellen. Bei geräten der Typenreihe EV ist werkseitig ein Abgleichkanal vorprogrammiert. Um diesen Kanal einzuschalten, müssen die beiden mit TEST bezeichneten Stifte auf der Logikplatine durchverbunden werden.
3. Zwischen den Stiften 4 und 5 (Masse) von J5 einen NF-Lastwiderstand von 2 Ohm anschließen. Die NF über diesen Widerstand wird als Prüfspannung herangezogen.
4. Die Spulenkerne der sieben Eingangsspulen (L1 bis L7) bis zur Oberkante der Platine eindrehen.
5. Ein Gleichspannungsvoltmeter zwischen dem Oszillatorprüfpunkt L0 und Masse anschließen.
6. Die Spulen L6, L5 und L7 in dieser Reihenfolge auf maximale Prüfspannung (typ. 2,1...3,5 V) abgleichen und wiederholen, bis keine weitere Zunahme der Anzeige erzielt wird.
7. An der Antennenbuchse des Gerätes einen Meßsender anschließen, so daß das Empfängerrauschen vom unmodulierten Meßsendersignal vollständig unterdrückt wird.
8. Zwischen dem ZF-Prüfpunkt IF und Masse ein NF-Voltmeter mit einem Frequenzbereich von mindestens 500 kHz anschließen (z.B. HP331A Distorsion Analyzer). Das Ausgangssignal des Meßsenders ständig solange erhöhen, bis am Voltmeter eine Prüfspannung von 30 mV eff. abgelesen wird. Danach die Spulen L1 bis L5 auf Maximalanzeige abgleichen und dabei das Ausgangssignal des Meßsenders während des Abgleichvorganges ständig soweit verringern, daß die Anzeige immer etwa 30 mV eff. bleibt. Der Abgleichvorgang wird sofort wiederholt, bis keine Verbesserung mehr erzielt werden kann.
9. Den Ausgangspegel des Meßsenders auf 1 mV einstellen.
Modulationsfrequenz: 1 kHz.
Hub:

 $\pm 3,0$ kHz bei 25 kHz Kanalabstand
 $\pm 2,4$ kHz bei 20 kHz Kanalabstand
 $\pm 1,5$ kHz bei 12,5 kHz Kanalabstand.

Am Lautstärkeregler eine NF-Ausgangsspannung (am 2 Ohm Lastwiderstand) von 1 V einstellen. Dann langsam die Spule des Quadraturdetektors L54 auf maximale NF-Ausgangsspannung einstellen.

10. Die Rauschsperrre wird wie folgt eingestellt:
 - a) R59 (SQCH) an den linken Anschlag drehen.
 - b) Ein HF-Signal mit einer Amplitude von 1 mV einspeisen.
Modulationsfrequenz: 1 mV.
Hub:

$\pm 3,0$ kHz bei 25 kHz Kanalabstand
 $\pm 2,4$ kHz bei 20 kHz Kanalabstand
 $\pm 1,5$ kHz bei 12,5 kHz Kanalabstand.

ABGLEICHANLEITUNG 136 - 174 MHz, STORNOPHONE 5500

- c) Am Lautstärkeregler ein Ausgangssignal von 1,7 V am 2 Ohm Lastwiderstand einstellen.
- d) Den HF-Eingangspegel verringern, bis ein SINAD-Wert von 10 dB (bewertet gemäß CCITT) erzielt wird.
- e) Mit der entsprechenden Taste auf der Frontplatte die Rauschsperre ausschalten.
- f) Den Rauschsperrenregler zuerst langsam nach rechts drehen, bis das Empfängerrauschen gerade verschwindet, und danach langsam in entgegengesetzter Richtung, bis das Rauschen gerade wieder hörbar wird.
- g) Das Eingangssignal zuerst auf null drehen und dann langsam erhöhen, bis der Empfänger gerade öffnet. In diesem Zustand muß der CCITT bewertete SINAD-Wert zwischen 8 und 12 dB liegen. Ggf. R59 geringfügig nachgleichen.

RÉGLAGE

STORNOPHONE 5500, 136 - 174 MHz

REMARQUE

Pendant le réglage, ne transmettre qu'en cas de nécessité.

REMARQUES GENERALES

Effectuez le réglage avec une tension d'alimentation de 13,2 V $\pm 0,1$ V c.c., sauf indication contraire dans les instructions. Dans le cadre de ces instructions, la rotation des potentiomètres sous-entend que l'on regarde le côté composants de la platine. Les emplacements des composants réglables sont présentés sur un diagramme en fin du chapitre.

Lorsque vous effectuez les procédures présentées dans les paragraphes suivantes, l'appareil doit être complètement assemblé à l'exception du couvercle du synthétiseur et le boîtier. Lorsque vous avez fini le réglage, installez toutes les couvercles et le boîtier avant de tester l'appareil aux spécifications

APPAREILS DE MESURE RECOMMANDÉS:

R2001	Communications Service Monitor, ou
R2200	Service Monitor
GTF180	Testeur mobile, avec
GTF244	Câble adaptateur pour CQM5500
PFT4053	Filtre Psophometrique
FTP3005	Unité d'essai cinq tonalités (non requis avec R2001.)
R1011	Bloc d'alimentation, ou
S1347	Bloc d'alimentation (pour émetteurs avec puissance HF inférieure à 10 W)
R1037	Multimètre numérique, ou
R1024	Multimètre numérique.

REGLAGE DE L'EMETTEUR

1. Pré-consignez les potentiomètres comme suit:

- * R453 (HI PWR) à fond à gauche
- * R455 (LO PWR) à fond à gauche
- * R463 (VOLT LIMIT) à fond à droite

RÉGLAGE 136 - 174 MHz, STORNOPHONE 5500

2. Ajustez la tension d'alimentation à 13,2 V \pm 0,1 V.
3. Choisissez le canal d'émission ayant la fréquence la plus élevée.
4. Branchez la sortie de l'émetteur à un wattmètre fournissant une charge de 50 Ohm.
5. Branchez un voltmètre cc entre le point de mesure SL et la masse. L'impédance du voltmètre doit être de 11 Megohm ou plus.
6. Transmettez et ajustez L210 jusqu'à ce que le voltmètre affiche 7,0 V cc
7. Choisissez le canal de fréquence d'émission la plus basse. Vérifiez que la tension cc soit au moins 2,5 V en transmettant.
8. Choisissez un canal quelconque (en cas d'appareil avec option MAB889 un canal haute puissance).
9. Transmettez et ajustez R453 (HI PWR) pour une puissance HF comme suit:

Modèle	Puissance HF
MAU0	1,0 W
MAU1	6,0 W
MAU2	10,0 W
MAU3	25,0 W

10. Passez en émission sur tous les canaux (tous les canaux haute puissance pour MAB889). Pour chaque canal, transmettez et notez la puissance de sortie. Pour les modèles MAU0, MAU2 et MAU3, notez le canal produisant la puissance de sortie minimale; pour MAU1 notez le canal produisant la puissance de sortie maximale. Si plus d'un canal produit la même puissance de sortie minimale ou maximale, choisissez l'un quelconque de ces canaux.
11. Passer en émission sur tous les canaux (tous les canaux haute puissance pour MAB889). Sur chaque canal, transmettez en surveillant la tension cc à la broche 4 du connecteur P6, ou au point de mesure CV sur la platine de commande. Notez le numéro du canal produisant la tension la plus forte, et la valeur de cette tension. Si plus d'un canal produit la même tension maximale, choisissez l'un quelconque des canaux. Si cette valeur est supérieur à 100 V cc, passer à l'opération 14. Sinon, passez à l'opération 12.
12. Sur le canal ayant produit la tension cc la plus forte lors de l'opération 11, tournez le potentiomètre VOLT LIMIT (R463) à fond vers la gauche. Tournez le potentiomètre HI PWR (R453) à fond vers la droite.
13. Transmettez et ajustez R463 pour une tension cc de 2,0 V plus forte que le niveau de tension noté lors de l'opération 11, et mesuré à la broche 4 du connecteur P6 ou au point de mesure CV.
14. Consignez le sélecteur de canal au canal noté lors de l'opération 10. Transmettez et ajustez le potentiomètre HI PWR (R453) pour:

Modèle	Puissance HF
MAU0	1,1 W
MAU1	5,6 W
MAU2	10,7 W
MAU3	25,0 W

15. Vérifiez que tous les canaux (tous les canaux haute puissance pour MAB889) produisent au moins 1,0 W, 10,0 W, ou 25,0 W, comme requis, pour les modèles MAU0, MAU2 et MAU3. Vérifiez qu'aucun canal ne produise plus de 6,0 W pour les modèles MAU1.

RÉGLAGE 136 - 174 MHz, STORNOPHONE 5500

16. Si l'appareil comprend l'option MAB889, choisissez un quelconque canal basse puissance. Transmettez et ajustez R455 (LO PWR) pour produire une puissance de sortie de 1,0 W (ou toute autre consigne de puissance spécifiée) pour les modèles MAU1 et MAU2. Vérifiez que la puissance de sortie HF pour tous les canaux basse fréquence tombe entre 0,7 W et 1,4 W. Réajustez légèrement R455 si nécessaire. Pour les modèles MAU0, ajustez R455 pour obtenir une puissance de 0,1 W ou toute autre puissance spécifiée. Vérifiez que la puissance de sortie pour tout canal basse puissance tombe entre 70 mW et 140 mW.

REGLAGE DE L'OSCILLATEUR DE REFERENCE

1. Branchez un compteur de fréquence précis par l'intermédiaire d'un atténuateur convenable sur la prise d'antenne.
2. Choisissez un quelconque canal d'émission.
3. Transmettez et ajustez L151 (R163 dans les modèles 2 ppm) jusqu'à ce que la fréquence d'émission ± 100 Hz sera affichée.
4. Vérifiez tous les canaux pour vous assurer de la programmation correcte des fréquences d'émission.

AJUSTAGE DE L'EXCURSION EN FREQUENCE

1. Branchez la prise d'antenne sur un compteur de fréquence précis par l'intermédiaire d'un atténuateur convenable.
2. Branchez un générateur B.F. ayant une impédance de sortie de 600 Ohm sur l'entrée microphone (voir figure 3). Consignez la fréquence du générateur sur 1 kHz et le niveau de sortie sur 800 mV efficaces.

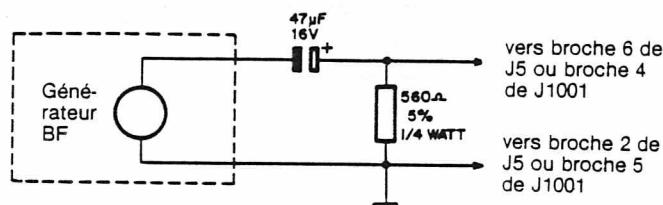

Figure 1
Branchement du générateur BF sur l'entrée microphone

3. Pré-consignez les potentiomètres R302 (VCO MOD) et R305 (REF MOD) à fond vers la gauche.
4. Choisissez un canal d'émission ayant une fréquence près du milieu de la gamme. Pour les modèles "Private-Line", choisissez un canal transmettant la tonalité "Private-Line".

RÉGLAGE 136 - 174 MHz, STORNOPHONE 5500

- Passez en émission et tournez R302 pour obtenir:

± 4,6 kHz (espacement 25 kHz)
± 3,7 kHz (espacement 20 kHz)
± 2,3 kHz (espacement 12,5 kHz)

REMARQUE

Si les lectures d'excursion positive et négative diffèrent, utilisez seulement la lecture supérieure.

- Pour les modèles à espacement entre voies de 25 kHz seulement, la procédure est terminée. Pour les autres modèles, passez à l'opération 7.
- Changez la fréquence du générateur BF à 200 Hz, et maintenez le niveau de sortie à 0,8 V.
- Transmettez et observez la forme d'onde sur un oscilloscope branché sur la sortie démodulée d'un récepteur d'essai. Ce récepteur devrait être non-atténué, et il doit y avoir un couplage cc entre le récepteur et l'oscilloscope (un couplage alternatif convient si la fréquence de coin est de 2 Hz ou moins). Tournez R305 (REF MOD) pour produire la réponse onde carrée la plus plate avec une inclinaison minimale.
- Retournez la fréquence du générateur BF à 1 kHz, 0,8 V efficace, et répétez l'opération 5.

REGLAGE DU RECEPTEUR

ATTENTION

Ajustez l'oscillateur VCO de l'émetteur et l'oscillateur de référence (voir les sections: REGLAGE DE L'EMETTEUR et REGLAGE DE L'OSCILLATEUR) avant de procéder à l'alignement du récepteur.

VCO DU RÉCEPTEUR

- Branchez un voltmètre c.c. de haute impédance (11 MegOhm minimum) entre le point de mesure SL et la masse.
- Appareils multicanaux: Choisissez le canal de réception ayant la fréquence la plus basse.
- Ajustez la bobine VCO (L201) pour obtenir une affichage de 7,0 V c.c.

RÉCEPTEUR

- Trouvez la fréquence d'accord (f_{accord}) comme suit:
 - Pour les récepteurs monocanal et multicanal avec de fréquence de réception unique:

$$f_{\text{accord}} = f_{\text{réception}}$$

RÉGLAGE 136 - 174 MHz, STORNOPHONE 5500

- b) Pour les appareils multicanaux ayant une largeur de bande réceptrice de 2 MHz ou moins:

$f_{\text{accord}} = \text{fréquence du canal de plus haute fréquence}$

- c) Pour les appareils multicanaux ayant une largeur de bande de réception de plus de 2 MHz mais moins de 4 MHz (inclus), trouvez f_{accord} comme suit:

$$f_{\text{accord}} = (f_{\text{haut}} + f_{\text{bas}}) : 2$$

Si l'un des canaux a une fréquence à moins de 500 kHz de f_{accord} , effectuez l'accord sur ce canal. Sinon, vous devrez obtenir une puce PROM d'accord (seulement pour les modèles EZ).

2. Consignez le sélecteur de canal au canal de la fréquence d'accord déterminée lors de l'opération ci-dessus. La fréquence d'accord est pré-programmée dans les modèles EZ. Pour le réglage sur f_{accord} , il suffit de court-circuiter les deux bornes d'essai TEST sur la platine de commande.
3. Branchez une charge résistive entre les broches 4 et 5 de J5. Surveillez la sortie audio dans cette charge résistive.
4. Pré-consignez les noyaux des sept bobines L1 à L7 de niveau avec la platine.
5. Branchez un voltmètre c.c. entre le point de mesure LO et la masse.
6. Ajustez les bobines L6, L5 et L7 dans cet ordre pour produire une tension c.c. maximale, typiquement entre 2,1 et 3,5 V c.c. Répétez cette opération jusqu'à ce que vous ne puissiez plus augmenter cette valeur.
7. Branchez un générateur HF (non modulé) sur le connecteur d'antenne, calé sur la fréquence de trafic. Réglez le niveau de sortie pour étouffer le récepteur.
8. Branchez un voltmètre c.a. avec une largeur de bande d'au moins de 500 kHz (un analyseur de distorsion HP331A par exemple) entre le point de mesure IF et la masse. Augmentez la sortie de générateur jusqu'à ce que le voltmètre c.a. indique environ 30 mV. Tournez les noyaux des bobines L1, L3, L4, et L5 jusqu'à ce que le voltmètre atteigne le maximum. Réduisez le niveau de sortie du générateur comme requis pour maintenir 30 mV eff. sur l'appareil lors de cette procédure. Répétez cette mise à point jusqu'à ce que vous ne puissiez plus faire augmenter la tension de mesure.
9. Consignez le niveau de sortie du générateur à 1 mV. Modulez-le avec une tonalité de 1 kHz à une excursion de fréquence de:

$$\begin{aligned} &\pm 3,0 \text{ kHz (espacement 25 kHz)} \\ &\pm 2,4 \text{ kHz (espacement 20 kHz)} \\ &\pm 1,5 \text{ kHz (espacement 12,5 kHz)} \end{aligned}$$

Ajustez la commande de volume pour produire un niveau audio d'environ 1 V eff. sur la charge de 2 Ohm. Ajustez lentement la bobine L52 pour produire un signal audio maximal.

10. Ajustez le squelch comme suit:
 - a) Pré-consignez le potentiomètre R59 (SQCH) à fond vers la gauche.
 - b) Appliquez un signal HF, modulé d'un ton de 1 kHz à un niveau de 1 mV et une excursion en fréquence de:

$$\begin{aligned} &\pm 3,0 \text{ kHz (espacement 25 kHz)} \\ &\pm 2,4 \text{ kHz (espacement 20 kHz)} \\ &\pm 1,5 \text{ kHz (espacement 12,5 kHz).} \end{aligned}$$

RÉGLAGE 136 - 174 MHz, STORNOPHONE 5500

- c) Ajustez la commande de volume pour produire un niveau audio d'environ 1,7 V eff. sur la charge de 2 Ohm.
- d) Réduisez le niveau de sortie du générateur jusqu'à ce qu'une valeur SINAD de 10 dB (mesurée selon CCITT) soit obtenu.
- e) Coupez le squelch par la touche correspondante sur le panneau avant.
- f) Tournez le squelch vers la droite jusqu'à ce que le bruit de fond cesse. Puis, tournez dans le sens inverse jusqu'à ce que le bruit redevienne tout juste audible.
- g) Réduisez le niveau de sortie du générateur à zero ce que le bruit devient audible, et vérifiez que la valeur SINAD (mesurée selon CCITT) se trouve entre 8 et 12 dBQ. Reajustez R59 un peu si requis.

GLD6165/GLD6166 RF BOARD 25 kHz CHANNEL SPACING

GLD6169/GLD6170 RF BOARD 12.5 kHz CHANNEL SPACING

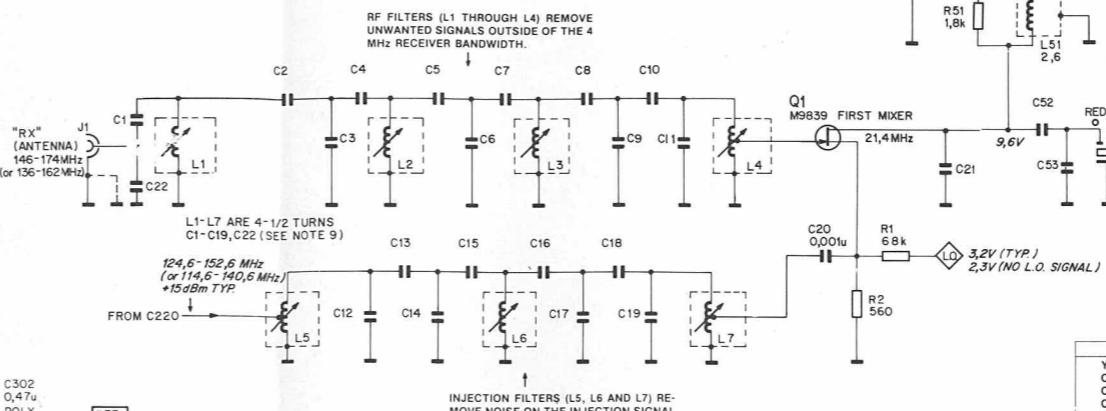

COMPONENT LAYOUT

D405.147/2

U51 INTERNAL BLOCK DIAGRAM

TRANSMIT AUDIO MODULATES
REFERENCE OSCILLATOR FREQUENCY
TO PREVENT THE SYNTHESIZER
LOOP FROM CANCELLING LOW-
FREQUENCY MODULATION APPLIED
TO THE VCO.

RF FILTERS (L1 THROUGH L4) REMOVE
UNWANTED SIGNALS OUTSIDE OF THE 4
MHz RECEIVER BANDWIDTH.

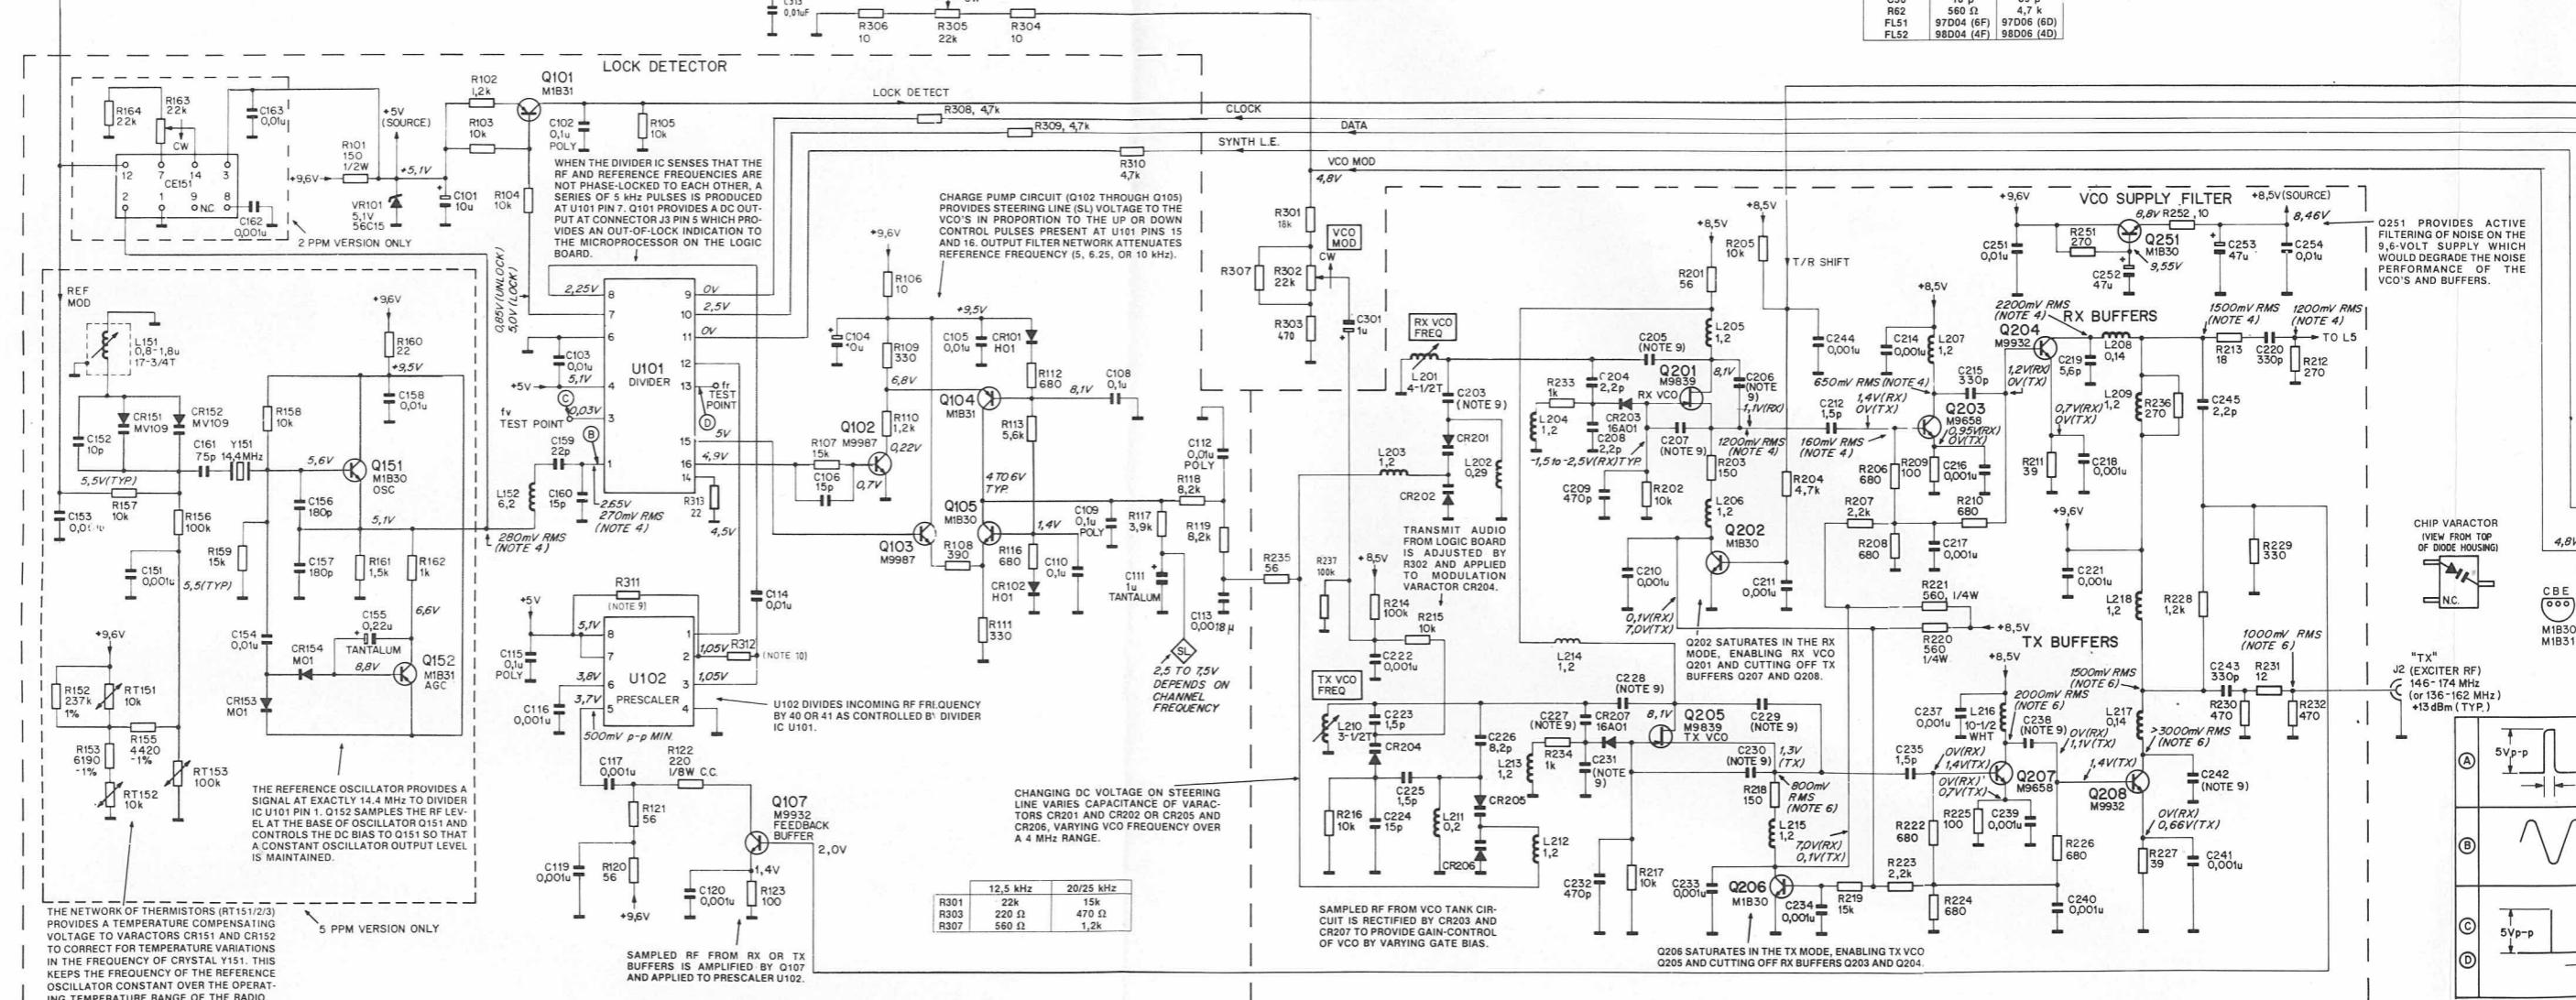

L1-L7 ARE 4-1/2 TURNS
C1-C19, C22 (SEE NOTE 9)

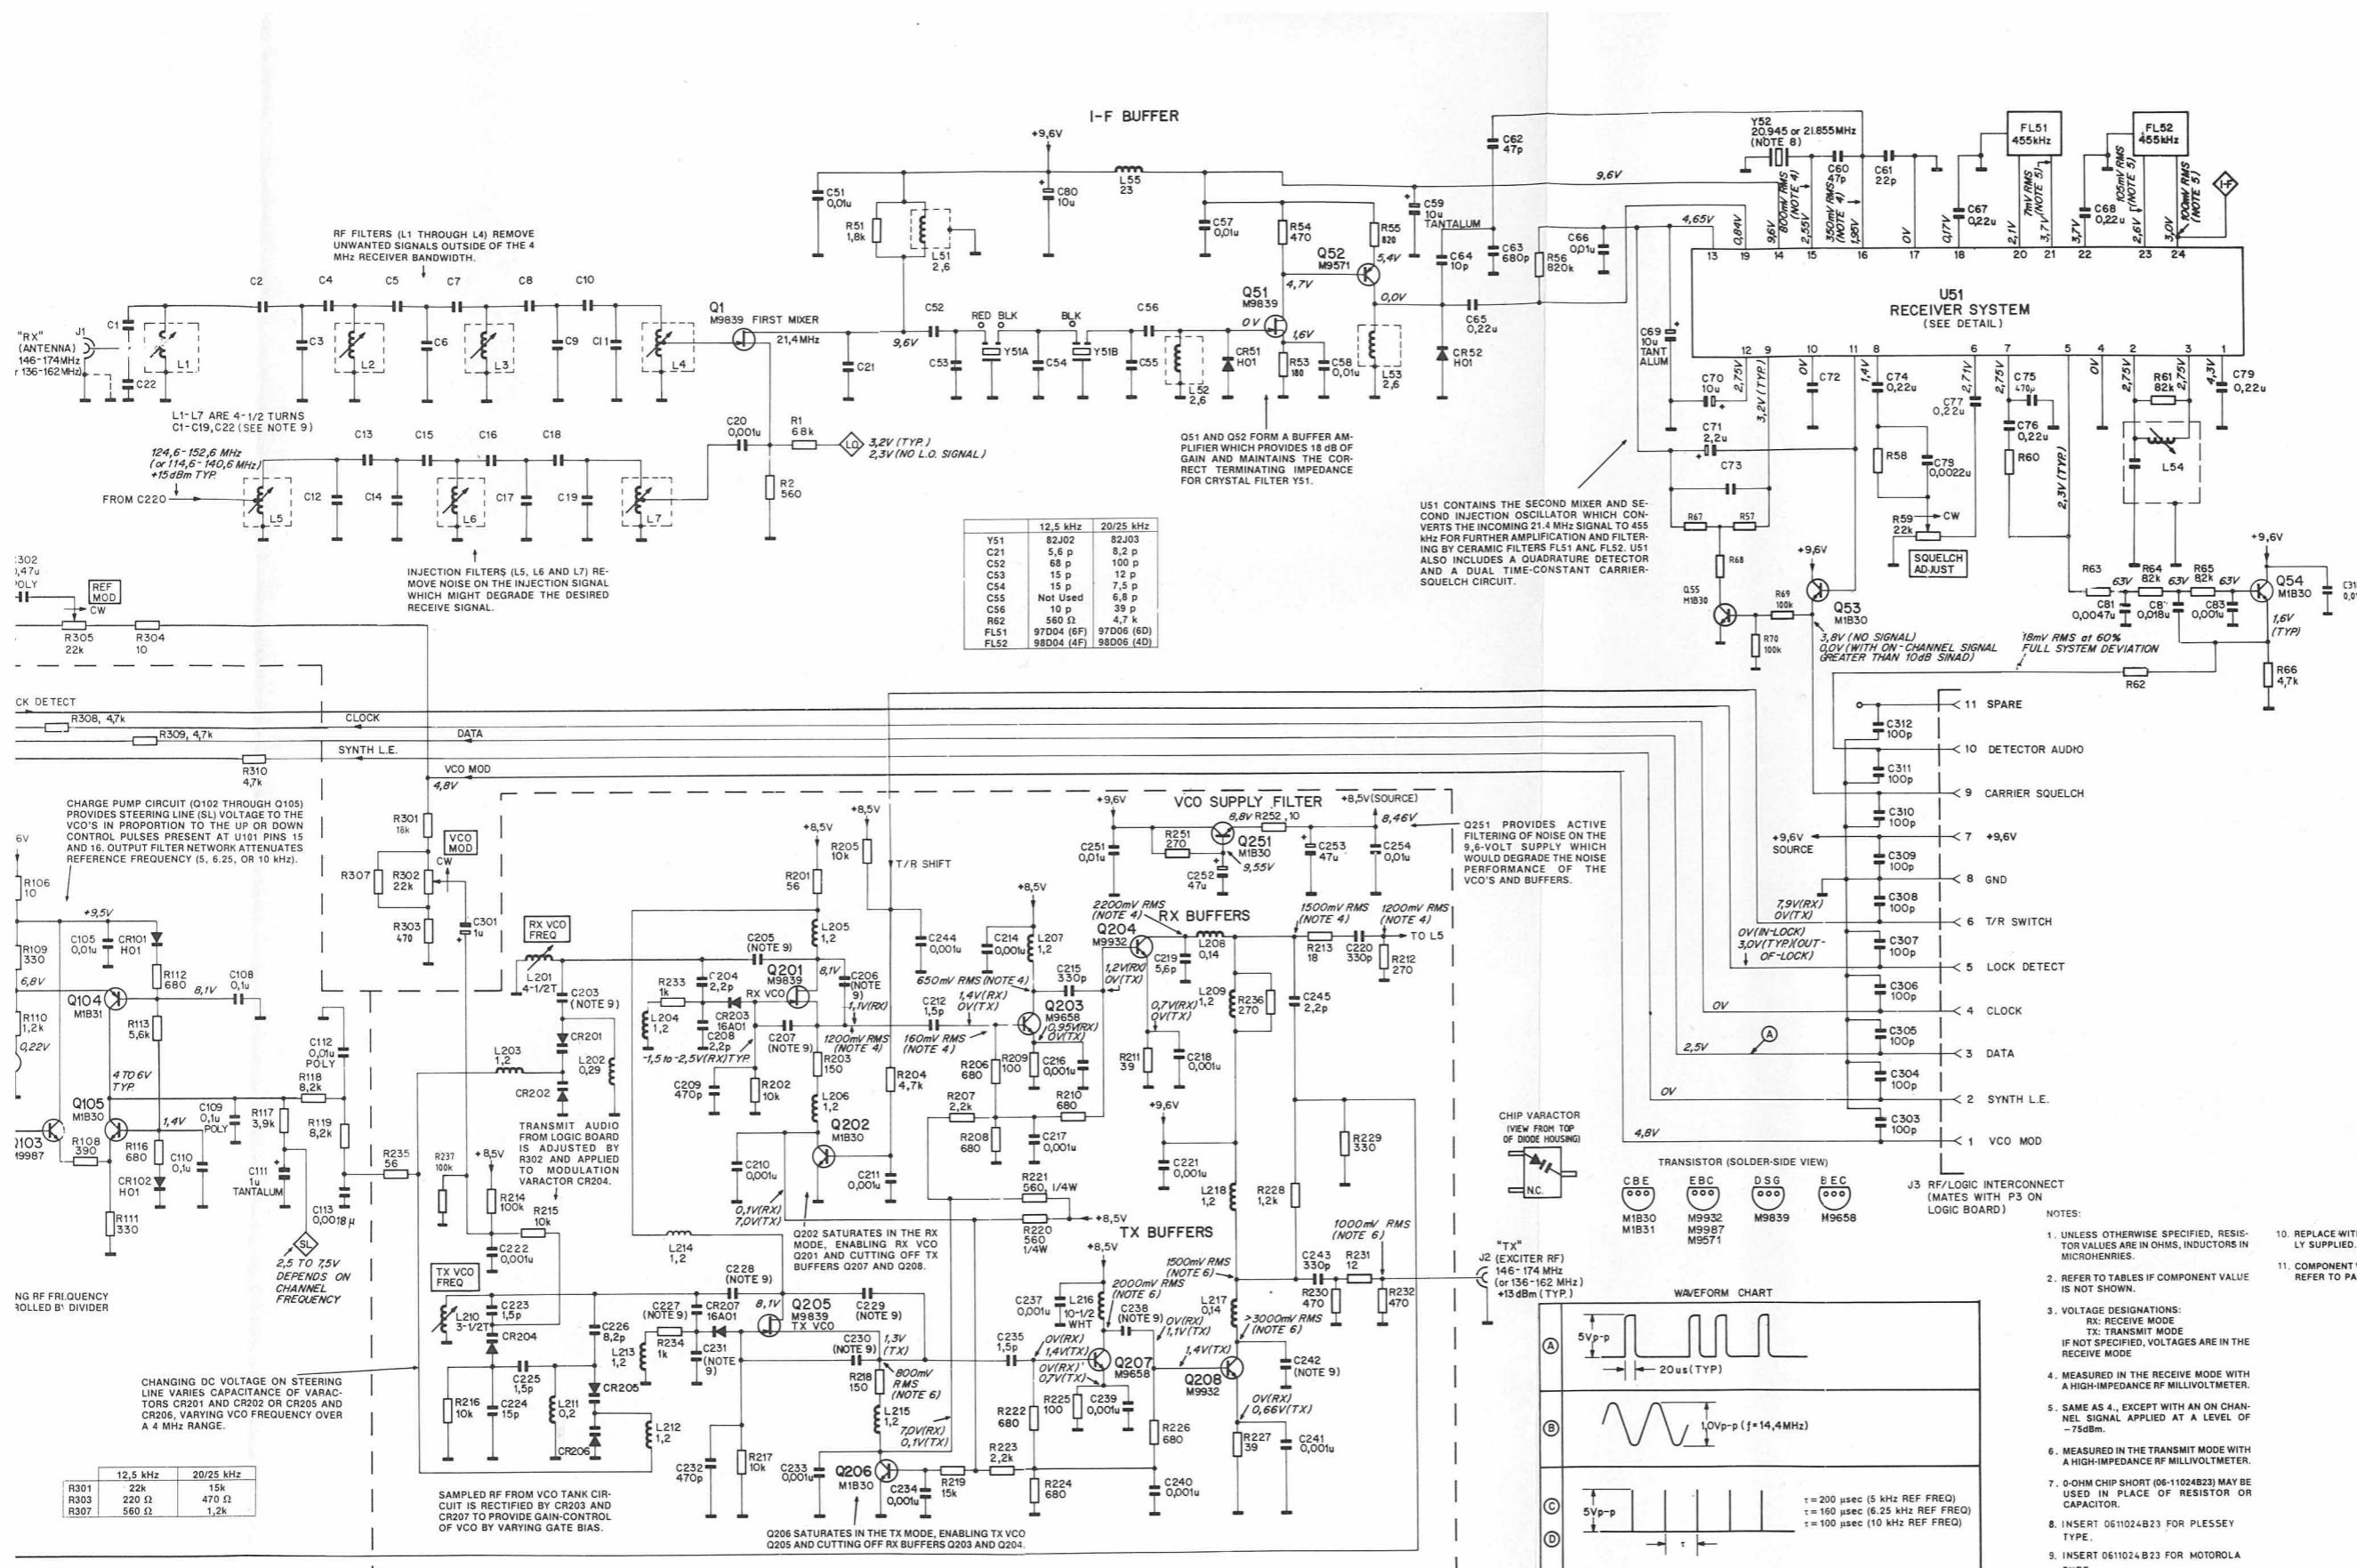

124.6-152.6 MHz
(or 114.6-140.6 MHz)
+15dBm TYP

INJECTION FILTERS (L5, L6 AND L7) REMOVE
NOISE ON THE INJECTION SIGNAL
WHICH MIGHT DEGRADE THE DESIRED
RECEIVE SIGNAL.

U51 CONTAINS THE SECOND MIXER AND
SECOND INJECTION OSCILLATOR WHICH CON-
VERTS THE INCOMING 21.4 MHz SIGNAL TO 455
kHz. THIS IS FOLLOWED BY A 4.6V BUFFER
AMPLIFIER (Q51) AND A 4.6V TANTALUM
CRYSTAL FILTER (Y51).

GLN6616 CONTROL HEAD DISPLAY BOARD GLN6618 INTERCONNECT BOARD COMPONENT LAYOUT

D405.141

NOTES:

1. UNLESS OTHERWISE SPECIFIED, ALL RESISTOR VALUES ARE IN OHMS.
2. PIN 9 OF P1002/J1002 IS THE BOARD TO BOARD STATIC GROUND INTERCONNECT.
3. DC TEST VOLTAGES ARE SHOWN WITH THE FOLLOWING CONDITIONS: F1 SELECTED, SW1005 CLOSED, SW1002 CLOSED.
4. CIRCUITRY SHOWN IN DASHED BOXES IS LOCATED ON THE DISPLAY BOARD VIA THE P1002/J1002 INTERCONNECTION.

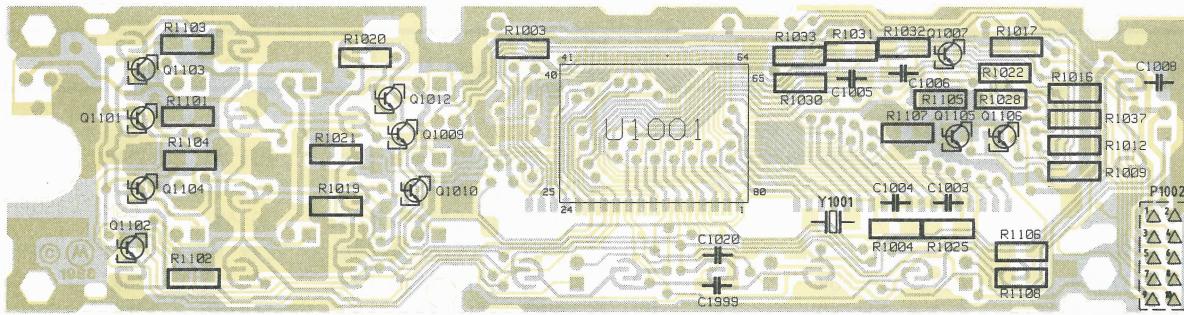

GDW - 1575-0

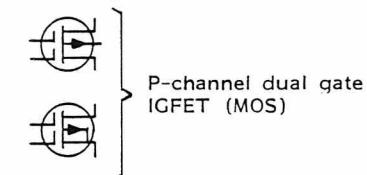

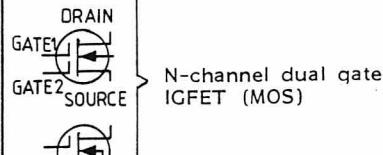

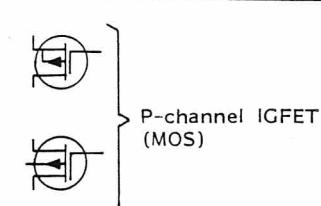

GRAPHICAL SYMBOLS USED IN CIRCUIT DIAGRAMS

Resistors(R)

-  Resistor
-  Resistor with fixed tap
-  Variable resistor
-  Resistor with movable tap (Potentiometer).
-  Varistor (voltage-dependent resistor)
-  NTC Temperature-dependent resistor with negative temperature coefficient
-  Light-emitting diode (photosensitive resistor)
-  PTC Temperature dependent resistor with positive temperature-coefficient.
-  Resistor with preset adjustment

Diodes(D)

-  Diode
-  Bridge rectifier
-  Series-connected stabilizer diodes within one case
-  Light-emitting diode
-  Zener diode (unidirectional)
-  Zener diode (bidirectional)
-  Tunnel diode
-  Backward diode
-  Varactor diode
-  Controlled rectifier, PNPN (N-thyristor)
-  Controlled rectifier, NPNP (P-thyristor)
-  Zener diode-programable.

Integrated Circuits(U)

Several integrated circuits contained within one case are designated by one common number followed by an identifying letter (a, b, c, etc.). Thus, circuits U1A, U1B and U1C are contained within one case.

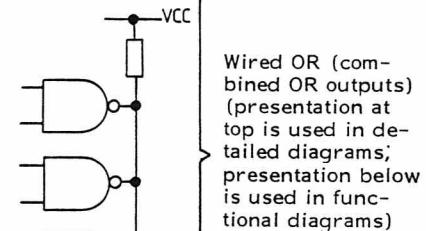

Capacitors(C)

-  Capacitor
-  Variable capacitor
-  Trimmer capacitor
-  Feedthrough capacitor
-  Electrolytic capacitor polarized
-  Polarized capacitor general
-  Electrolytic capacitor non-polarized

Transistors(Q)

-  Transistor, PNP
-  Transistor, NPN
-  Light-sensitive transistor PNP
-  Unipolar transistor with N-type base

Gates

Coils(L)

-  RF coil, air core
-  Coupled RF coils, air core
-  RF coil with adjustable core
-  Coil with tap.
-  Helical-coil.

Junction Field Effect Transistors (JFET)

-  N-channel JFET
-  P-channel JFET
-  N-channel dual gate JFET
-  P-channel dual gate JFET

Insulated Gate Field Effect Transistors (IGFET or MOS)

-  N-channel IGFET (MOS)

Transformers(T)

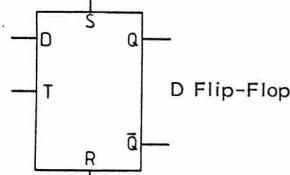

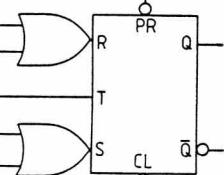

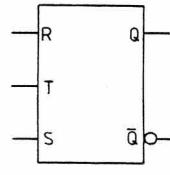

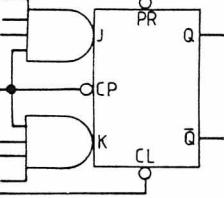

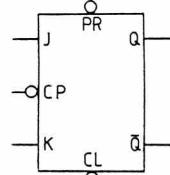

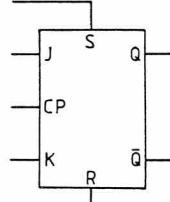

-  Transformer with iron core
-  Transformer with adjustable RF cores

GRAPHICAL SYMBOLS USED IN CIRCUIT DIAGRAMS

Flip-flops

Abbreviations used:

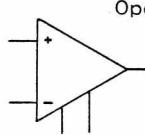

S =Set
R =Reset
CP=Clock pulse
PR=Preset
CL=Clear
T =Toggle

Inverters

Operational Amplifiers

Operational amplifiers.

Relays(K)

Single-coil relay

Dual-coil relay

Polarized relay

Slow-acting relay

Slow-release relay

Contacts

Open contact (make)

Closed contact (break)

Change-over contact

Change-over contact centre off

Make-before-break

Switches and Keys(S)

On/Off switch

Locking keys or switches:
push on, push off

Locking keys or switches:
push on, push off

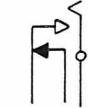

Non-Locking self-releasing

Non-Locking self-releasing

Non-Locking self-releasing

Make-before-break

Locking mutually releasing
keys or switches (In row
of push-buttons etc.)

Rotary switch.

ON/OFF switch electrically
controlled.
(Not a relay)

Lamps(V)

Indicator Lamp.

Neon Lamp

Fuses and Cut-outs(F)

Fuse

Circuit breaker

Batteries(B)

Battery one cell

Battery multi cell

Feedthrough Filters(Z)

Feedthrough filter

Ferrite Beads(FB)

Ferrite bead

Crystals(Y)

Crystal

Cables and Wires(W)

— Usual conductor.

— Three conductors

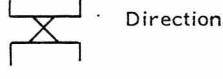

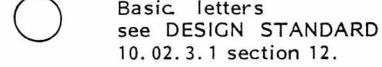

— Eight conductors.

— Shift from multiple-line to
single-line presentation.

— Screened cable.

— Coaxial cable.

GRAPHICAL SYMBOLS USED IN CIRCUIT DIAGRAMS

Connectors(J and P) <p>  Female (socket) connector.  Male (plug) connector  Multi-wire connector.  Coaxial plug.  Coaxial socket. </p>	Replaceable Connections(W) <p>  Cross-field connection. (jumper).  Strap. </p>	
Loudspeakers(LS) <p>  Loudspeaker.  Loudspeaker-Microphone. </p>	Miscellaneous <p>  Antenna  Buzzer.  Horn.  Directional Coupler. </p>	
Telephones(TEL) <p>  Telephone.  Single headphone. (Earphone).  Double headphone. </p>	<p>  Circulator.  Multiconductor bus (used in logic diagrams) * = Identifying bus label e.g. DATA, ADDRESS....  Chassis or frame connection </p>	
Microphones(M) <p>  Microphone. </p>	<p>  Grouping of leads.  Crossing of wires. </p>	
Meters etc. <p>  Indicating instrument.  Balancing instrument. (Galvanometer).  Basic letters see DESIGN STANDARD 10.02.3.1 section 12. </p>	<p>  Junction of connected wires </p>	
Test Points <p>  DC test point.  AC test point. </p>
